Introduction au non-contact AFM (ou FM-AFM)

Non-contact

Tapping

Modélisation

Introduction

nc-AFM vs. “Tapping” ou modulation de fréquence vs. modulation d’amplitude

Réelle méthode de non-contact

Sensibilité verticale très supérieure au “Tapping”

Méthode de découplage efficace des forces conservatives et dissipatives (pourvu que la phase soit bien maintenue)

Affranchissement de la constante de temps liée au facteur de qualité

Technique essentiellement UHV (requiert Q élevé)

Contribution potentielle de l’électronique aux signaux de mesure !

Le non-contact AFM

Non-contact

Tapping

Modélisation

Introduction

Phase fixée ($= -90^\circ$) et
amplitude d'oscillation fixée
(modulation de fréquence)

Mesures : décalage de la fréquence
de résonance et amplitude
d'excitation requise pour conserver
l'amplitude d'oscillation constante
en fonction de la distance pointe-
surface

Asservissement : décalage donné de la
fréquence de résonance

Mesure d'effets dissipatifs en nc-AFM

- Energie dissipée par un oscillateur harmonique

$$Q = 2\pi \frac{\langle E_{stored} \rangle_T}{\langle E_{diss} \rangle_T} \Leftrightarrow \langle E_{diss} \rangle_T = 2\pi \frac{\langle E_{stored} \rangle_T}{Q} \Rightarrow \langle E_{diss} \rangle_T = \pi \frac{kA_0^2}{Q} = \pi k A_0 A_{exc} = \pi \frac{kA_0^2 \Gamma_0}{\omega_0}$$

$$A_{exc} \propto \langle E_{diss} \rangle_T \propto \Gamma_0$$

Mesure d'effets dissipatifs en nc-AFM

Non-contact

Tapping

Modélisation

Introduction

- Le cas du nc-AFM :

Vertical distance

D_1

D_2

A_{exc} variée

$$Q_0(D_1) = \frac{\omega_0}{\Gamma_0(D_1)}$$

$$Q_{eq}(D_2) = \frac{\omega_0^{nl}}{\Gamma_{eq}(D_2)} \approx \frac{\omega_0}{\Gamma_0 + \Gamma_{int}},$$

avec $\Gamma_{eq} > \Gamma_0$, donc $Q_{eq} < Q_0$

$$Q_{eq} = 2\pi \frac{\langle E_{stored} \rangle_T}{\langle E_{diss} \rangle_T}$$

En nc-AFM, A_0 étant constante $\rightarrow$ mesure de la dissipation en non-contact

$$\langle E_{diss} \rangle_T = \pi k A_0 A_{exc} = \pi \Gamma_{eq}(D) \frac{k_0 A_0^2}{\omega_0} \Rightarrow$$

Les variations de A_{exc} pour conserver A_0 constante forment une image de "dissipation (ou damping)"

Ordres de grandeur (@RT) :

$$\begin{aligned} k &= 30 \text{ N/m} \\ A_0 &= 10 \text{ nm} \\ A_{exc} &= A_0/Q = 10/30000 \sim 0.3 \text{ pm} \end{aligned} \quad \langle E_{diss} \rangle_T = 2 \text{ eV/cycle}$$

(Received 11 April 2006; published 7 July 2006)

Identification of energy-dissipation processes at the nanoscale is demonstrated by using amplitude-modulation atomic force microscopy. The variation of the energy dissipated on a surface by a vibrating tip as a function of its oscillation amplitude has a shape that singles out the dissipative process occurring at the surface. The method is illustrated by calculating the energy-dissipation curves for surface energy hysteresis, long-range interfacial interactions and viscoelasticity. The method remains valid with independency of the amount of dissipated energy per cycle, from 0.1 to 50 eV. The agreement obtained between theory and experiments performed on silicon and polystyrene validates the method.

A nc-AFM simulator with PLL-controlled frequency detection and excitation : addressing the problem of apparent dissipation

(Received 23 March 2002; published 16 September 2002)

Numerical simulations of the frequency modulation atomic force microscope, including the whole dynamical regulation by the electronics, show that the cantilever dynamics is conditionally stable and that there is a direct link between the frequency shift and the conservative tip-sample interaction. However, a soft coupling between the electronics and the nonlinearity of the interaction may significantly affect the damping. A resonance between the scan speed and the response time of the system can provide a simple explanation for the spatial shift and contrast inversion between topographical and damping images, and for the extreme sensitivity of the damping to a tip change.

Block diagram of the electronics

Block diagram of the electronics

Features

- Description of the real setup (mix of analog/digital devices)
- LabView™ implementation (now C version available)
- GUI with tunable parameters at run time
- The Phase-Locked Loop (PLL) detects the frequency shift and provides the excitation signal to the cantilever

Results

Description

Introduction

Implementation

➤ Difficulties :

- Three (four) feedback loops: PLL, APIC, DPIC
- Various operating frequencies (many time constants)
- 3 controllers : 6 gains
- Non-linear problem with coupled components

➤ Assumptions :

- Analog components are solved with a modified Verlet's algorithm ($f_s = 400$ MHz)
- DACs and ADCs are “ideal” components
- PSD and preamp. not described
- No noise
- Any physical channel of dissipation is considered

Block diagram of the electronics

Block 1, the oscillator

- Analog device
- $f_s = f_{s0} = 200 \text{ MHz}$

Implementation :

$$\ddot{z}(t) + \frac{\omega_0}{Q}\dot{z}(t) + \omega_0^2 z(t) = \omega_0^2 \underline{A_{\text{exc}}(t)} + \frac{\omega_0^2 \underline{F_{\text{int}}(t)}}{k_c}$$

$$A_{\text{exc}}(t_i) = K_3 \times \underbrace{D_{\text{amp}}(t_i)}_{10 \text{ kHz}} \times \underbrace{z_{\text{ps}}(t_i)}_{20 \text{ MHz}}$$

$$F_{\text{int}}(t) = -\partial_{r(t)} V_{\text{int}}(r(t))$$

$$V_{\text{int}}(r) = -\frac{HR}{6r} - U_0 \left[2e^{-\frac{r-r_c}{\lambda}} - e^{-\frac{2(r-r_c)}{\lambda}} \right]$$

$$r(t_i) = D(t_i) - z(t_i)$$

BPF output :

$$\ddot{z}_{\text{bpf}}(t) + 2\pi B_W \dot{z}_{\text{bpf}}(t) + \omega_c^2 z_{\text{bpf}}(t) = 2\pi B_W \times K_1 \times \dot{z}(t)$$

↪ 50 kHz

Block diagram of the electronics

Block 2, the RMS-to-DC converter

- Analog device (PLL board)
- $f_s = f_{s_0} = 200$ MHz

Implementation :

$$\begin{cases} A_{\text{rms}}(t_i) = K_{\text{rms}} \times \sqrt{V_s(t_i)} \\ \tau_{\text{rms}} \dot{V}_s(t) + V_s(t) = V_e(t) \Rightarrow \tau_{\text{rms}} = 15.9 \mu\text{s} (f_{\text{co}}^{\text{lp}} = 10 \text{ kHz}) \\ V_e(t_i) = z_{\text{bpf}}^2(t_i) \end{cases}$$

The PLL receives :

$$\frac{z_{\text{bpf}}(t_i)}{A_{\text{rms}}(t_i)}$$

Block diagram of the electronics

Block 3, the amplitude controller (APIC)

- Digital device (DSP board)
- Provides the output signal @ $f_s = 10$ kHz

Implementation :

$$D_{amp}(t_i) = P_{ac} [A_0^{\text{set}} - A_{\text{rms}}(t_i)] + \sum_{j=0}^i I_{ac} [A_0^{\text{set}} - A_{\text{rms}}(t_j)] \Delta t_b$$

Saturation : $D_{amp} \in [0 ; 10\text{V}]$

Block diagram of the electronics

Block 4, the digital PLL

- Digital device (PLL board)
- $f_s = 20$ MHz

Implementation :

$$z_e(t_i) = \frac{z_{bpf}(t_i)}{A_{rms}(t_i)} \times \cos(\varphi_{nco}(t_i))$$

Frequency tracker

Disengaged, $\omega_{cent} = \text{constant}$

$$\varphi_{nco}(t_i) = \sum_{j=p11}^i [\omega_{cent} + K_0 u_f(t_j)] \Delta t_c$$

Engaged, ω_{cent} updated (@ 2.5 kHz)

$$\omega_{cent}(t_i) = \omega_{cent}(t_{i-1}) + K_0 \times u_f(t_{i-1})$$

$$\varphi_{nco}(t_i) = \sum_{j=p11}^i \omega_{cent}(t_j) \times \Delta t_c$$

Block diagram of the electronics

Block 5, the phase shifter

- Digital device (PLL board)
- $f_s = 20 \text{ MHz}$

Implementation :

$$\begin{aligned} z_{ps}(t_i) &= \sin(\varphi_{nco}(t_i)) \times \cos(\varphi_{ps}) + \cos(\varphi_{nco}(t_i)) \times \sin(\varphi_{ps}) \\ &= \sin(\varphi_{nco}(t_i) + \varphi_{ps}) \end{aligned}$$

Block diagram of the electronics

Block 6, the distance controller (DPIC)

Results

Description

Introduction

- Digital device (DSP board)
- Provides the output signal @ $f_s = 10$ kHz

Implementation :

$$D(t_i) = P_{dc} [\Delta f^{\text{set}} - \Delta f(t_i)] + \sum_{j=0}^i I_{dc} [\Delta f^{\text{set}} - \Delta f(t_j)] \Delta t_b$$

Virtual PLL

Dynamic properties of the APIC

Optimum conditions $t_{APIC} \sim 2.1$ ms

Approach curves : apparent damping (1)

- Contribution of the PLL locking time: varying $K_0 \times K_d$ (frequency tracker engaged)

$K_0 K_d = 100$; $t_{\text{lock}} > 5$ ms
 $K_0 K_d = 1000$; $t_{\text{lock}} \sim 2$ ms
 $K_0 K_d = 5000$; $t_{\text{lock}} \sim 0.35$ ms
 $K_0 K_d = 11000$; $t_{\text{lock}} < 0.2$ ms (nervous)

Intrinsic damping :
 $\langle E_{\text{diss}}^{\text{intr}} \rangle_T = 2$ eV/cycle

Apparent damping :
 $\langle E_{\text{diss}}^{\text{app}} \rangle_T = 14\% \langle E_{\text{diss}}^{\text{intr}} \rangle_T \cong 0.28$ eV/cycle

Approach curves : apparent damping (2)

- Contribution of the frequency tracker

Apparent damping :

$$\langle E_{diss}^{app} \rangle_T = 14\% \langle E_{diss}^{intr} \rangle_T \cong 0.28 \text{ eV/cycle}$$

Summary

- **PLL dynamics** : **major role** in the occurrence of relevant **apparent damping** if the **locking time is about or larger than 1~ms**, that is only twice faster than the APIC optimum response time
- The **frequency tracker**, the aim of which is to update the PLL center frequency to make it matching the actual resonance frequency, plays also a **major role** in the occurrence of **apparent damping**. It has to be engaged when performing approach curves
- The **PLL optimal locking time is about 0.35 ms that is 6 times shorter than the shortest APIC response time** of the free cantilever. Therefore **the resonance condition is expected to be always properly maintained**. Consequently, when the PLL operates properly, **no amplitude changes due to a bad tracking of the resonance frequency are expected to occur**
- The APIC response time seems to be limited to ~2 ms due to the RMS-to-DC converter

Scan lines (Δf regulation) (1)

- Contribution of the PLL

- Sinusoidally corrugated surface ($\lambda = 6.6 \text{ \AA}$)
- 256 points per line
- $v_x = 7 \text{ nm.s}^{-1}$, $P_{AC} = 10^{-3}$, $I_{AC} = 10^{-4} \text{ s}^{-1}$
- Frequency tracker engaged

➔ { Negligible effect on the topography
Negligible apparent damping except if PLL is slow

Scan lines (Δf regulation) (2)

• Contribution of the APIC

- Surface with opposite steps (height : 3.3 Å)
- 1024 points per line
- $v_x = 5 \text{ nm.s}^{-1}$, $K_0 \times K_d = 5000 \text{ rad.s}^{-1}$
- Frequency tracker engaged

➔ Negligible effect on the topography
Weak apparent damping (not experimentally relevant) provided APIC is fast

- 2 nm/s
- 5 nm/s
- 10 nm/s
- 20 nm/s

➔ { Distorted topography at high v_x
Weak apparent damping (not experimentally relevant)

Summary

- PLL dynamics : major role in the occurrence of relevant apparent damping if the locking time is about or larger than 1~ms, that is only twice faster than the APIC optimum response time
- The frequency tracker, the aim of which is to update the PLL center frequency to make it matching the actual resonance frequency, plays also a major role in the occurrence of apparent damping. It has to be engaged when performing approach curves
- The PLL optimal locking time is about 0.35 ms that is 6 times shorter than the shortest APIC response time of the free cantilever. Therefore the resonance condition is expected to be always properly maintained. Consequently, when the PLL operates properly, no amplitude changes due to a bad tracking of the resonance frequency are expected to occur
- The APIC response time seems to be limited to ~2 ms due to the RMS-to-DC converter
- **A weak contribution of the APIC to apparent dissipation is observed.** Although spatial shift and apparent dissipation can conditionally be generated, the overall strength of the effect remains weak and should hardly be measurable for UHV investigations at room temperature.

Is the apparent damping relevant?

Simplest assumption: what is the dissipated energy of the cantilever due to thermal fluctuations when oscillating close to the surface?

$$k_B T \Rightarrow \delta A_0 (\delta s) \Rightarrow \delta F_{\text{int}} (\delta \Delta f) \Rightarrow \delta A_{\text{exc}}$$

To first order:

$$\frac{\delta A_{\text{exc}}}{A_0} = \frac{\delta F_{\text{int}}}{k_c A_0} \Rightarrow \delta E_d = \pi A_0 \delta F_{\text{int}}$$

Δf is connected to F_{int} [1]:

$$\frac{\Delta f k_c A_0^{3/2}}{f_0} \simeq 0.43 \sqrt{V_{\text{int}}(r) F_{\text{int}}(r)} \Rightarrow \frac{\delta f}{f_0} \simeq \frac{0.43}{2k_c A_0^{3/2}} \sqrt{\frac{V_{\text{int}}(r)}{F_{\text{int}}(r)}} \delta F_{\text{int}}$$

The frequency noise is given by [2]:

$$\frac{\delta f}{f_0} = \sqrt{\frac{2k_B T B}{\pi^3 k_c A_0^2 f_0 Q}} \Rightarrow \delta E_d \simeq 4.6 \sqrt{\frac{2k_B T B k_c A_0^3 F_{\text{int}}(r)}{\pi f_0 Q V_{\text{int}}(r)}}$$

[1]- H.-J. Ke *et al.*, **Noncontact Atomic Force Microscopy**, Eds Morita, Wiesendanger, Meyer, Springer Berlin, Germany 2002

[2]- F.J. Giessibl, ch2 in ref.[1]

Is the apparent damping relevant?

Parameters : $A_0=7\text{nm}$, $f_0=150\text{ kHz}$, $k_c=40\text{ Nm}^{-1}$, $B=260\text{ Hz}$
interaction parameters taken from [1] at $s=5\text{ \AA}$

Q	E_0 (eV/cycle)	δE_d (eV/cycle)	$\delta E_d/E_0$	δE_d (eV/cycle)	$\delta E_d/E_0$
	VdW + short range			Pure VdW	
5000 ($T = 298^\circ\text{K}$)	7.69	0.177	2.30%	0.141	1.84%
30000 ($T = 298^\circ\text{K}$)	1.28	7.25×10^{-2}	5.65%	5.78×10^{-2}	4.50%
500000 ($T = 4^\circ\text{K}$)	0.077	2.06×10^{-3}	2.67%	1.64×10^{-3}	2.13%

- Apparent dissipation due to PLL would be detected if it would occur (15%)
- Gauthier *et al.* put in evidence effects that are in the 5% range, not relevant in UHV at room temperature! With the conditions given in his work:

$$\delta E_d/E_0 \sim 27\%$$

Does not explain the shift but dissipation observed at steps is likely real dissipation

[1]- R. Pérez *et al.*, Phys. Rev. B **58**, 10835 (1998)

Summary and Outlooks

- ✓ Implementation of the real setup
- ✓ Reasonable description of the dynamic properties of the PLL (amplitude controller as well)
- ✓ Relevant apparent dissipation can conditionally be observed (PLL gains and frequency tracker)

- ❑ Investigation of the stability
- ❑ Contribution of noise
- ❑ Realistic force fields (SciFi)
- ❑ Atomistic description of damping
- ❑ Calculation of images

Questions / Discussions

Dynamic properties of the APIC

Behavior of the APIC in the closed loop:

- Steady equation of the oscillator amplitude ($\varphi = -\pi/2$, $\omega = \omega_0$) :

$$G_{sys}(s) = \frac{K_1 A_0(s)}{A_{exc}(s)} = \frac{b}{s + a} \quad \left\{ \begin{array}{l} b = \frac{K_1 K_3 \omega_0}{2} \\ a = \frac{\omega_0}{2Q} \end{array} \right.$$

- P, I controller :

$$G_{APIC}(s) = K_P + \frac{K_I}{s}$$

$$\Rightarrow G_{cl}(s) = \frac{K_1 A_0(s)}{A_0^{ref}(s)} = \frac{G_{APIC}(s) G_{sys}(s)}{1 + G_{APIC}(s) G_{sys}(s)}$$

Dynamic properties of the APIC

The closed looped system is analogous to a second order system

$$\begin{cases} \text{Undercritically damped regime} \Rightarrow \zeta < 1 \Leftrightarrow c < \sqrt{bK_I} \\ \text{Critically damped regime} \Rightarrow \zeta = 1 \Leftrightarrow c = \sqrt{bK_I} \\ \text{Overcritically damped regime} \Rightarrow \zeta > 1 \Leftrightarrow c > \sqrt{bK_I} \end{cases} \quad c = \frac{a+bK_P}{2}$$

$$K_I = \frac{\omega_0}{8} \left(\frac{1}{Q} + K_1 K_3 K_P \right)^2$$

time constant
of the system?

Dynamic properties of the APIC

Analysis of the system response to a step :

$$\mathcal{L}^{-1} \curvearrowright G_s(s) = \frac{A_s}{s}$$

- Overcritically damped regime :

$$g_{cls}(t) = A_s \left\{ 1 + \frac{c-\xi-bK_P}{2\xi} e^{-\underbrace{(c+\xi)t}_{\text{Short time scales}}} - \frac{c+\xi-bK_P}{2\xi} e^{-(c-\xi)t} \right\} \quad \xi = \sqrt{c^2 - bK_I}$$

- Critically damped regime :

$$g_{cls}(t) = A_s \{ 1 - e^{-ct} + [bK_P - c] t e^{-ct} \}$$

- Undercritically damped regime :

$$g_{cls}(t) = A_s \left\{ 1 - e^{-ct} \times \left[\cos(\xi' t) + \frac{c-bK_P}{\xi'} \sin(\xi' t) \right] \right\} \quad \xi' = \sqrt{bK_I - c^2}$$

Dynamic properties of the APIC

Summary :

Remarks

- Time of calculation on a AMD 1700+, 512 Mb RAM
 - Approach curve: 15 nm vertical extension @ 2 nm.s⁻¹ ~ 45 min.
 - 1 scan line: 7 nm @ 5nm.s⁻¹ ~ 20 min.

Stability analysis of the linear closed looped system

Resonance condition: $\varphi = -\pi/2$, $\omega = \omega_0$

Routh-Hurwitz stability analysis $\Rightarrow$ 5 determinants : $\Delta_1, \Delta_2, \Delta_3, \Delta_4, \Delta_5$.
Must be **positive** for the system to be **stable**

Δ_1 and Δ_2 are unconditionally positive
