FOREWORD

Well-quasi-orderings (wqos) (Kruskal, 1972) are a fundamental tool in logic and computer science. They provide termination arguments in a large number of decidability (or finiteness, regularity, ...) results. In constraint solving, automated deduction, program analysis, and many more fields, wqo’s usually appear under the guise of specific tools, like Dickson’s Lemma (for tuples of integers), Higman’s Lemma (for words and their subwords), Kruskal’s Tree Theorem and its variants (for finite trees with embeddings), and recently the Robertson-Seymour Theorem (for graphs and their minors). What is not very well known is that wqo-based proofs have an algorithmic content.

The purpose of these notes is to provide an introduction to the complexity-theoretical aspects of wqos, to cover both upper bounds and lower bounds techniques, and provide several applications in logics (e.g. data logics, relevance logic), verification (prominently for well-structured transition systems), and rewriting. Because wqos are in such wide use, we believe this topic to be of relevance to a broad community with interests in complexity theory and decision procedures for logical theories. Our presentation is largely based on recent works that simplify previous results for upper bounds (Figueira et al., 2011; Schmitz and Schnoebelen, 2011) and lower bounds (Schnoebelen, 2010a; Haddad et al., 2012), but also contains some original material.

These lecture notes originate from an advanced course taught at the 24th European Summer School in Logic, Language and Information (ESSLLI 2012) on August 6–10, 2012 in Opole, Poland, and also provide background material for Course 2.9.1 on the mathematical foundations of infinite transition systems taught at the Parisian Master of Research in Computer Science (MPRI). They follow their own logic rather than the ordering of these courses, and focus on subproblems that are treated in-depth:

- **Chapter 1** presents how wqos can be used in algorithms,
- **Chapter 2** proves complexity upper bounds for the use of Dickson’s Lemma —this chapter is adapted chiefly from (Schmitz and Schnoebelen, 2011)—, and
- **Chapter 3** details how to derive Ackermannian lower bounds on decision problems, drawing heavily on (Schnoebelen, 2010a).
Additionally, Appendix A proves many results on subrecursive hierarchies, which are typically skipped in papers and presentations, but needed for a working understanding of the results in chapters 2 and 3, and Appendix B lists known problems of enormous complexities.

A relation $\leq$ over a set $A$ is a quasi ordering (qo) iff it is reflexive and transitive. A quasi-ordering is a partial ordering (po) iff it also antisymmetric ($x \leq y$ and $y \leq x$ imply $x = y$). Any qo induces an equivalence relation $\equiv \overset{\text{def}}{=} \leq \cap \geq$, and gives rise to a canonical partial ordering between the equivalence classes, and to a strict ordering $< \overset{\text{def}}{=} \leq \setminus \equiv$ between non-equivalent comparable elements. A qo is linear (aka total) iff any two elements are comparable ($\leq \cup \geq = A^2$). The main object of interest in this course is the following:

**Definition 1.1** (wqo.1). A well quasi ordering (wqo) $\leq$ over a set $A$ is a qo such that every infinite sequence $x_0, x_1, x_2, \ldots$ over $A$ contains an increasing pair: $\exists i < j$ s.t. $x_i \leq x_j$.

A well partial ordering is an antisymmetric wqo. By extension, a set along with an ordering $(A, \leq)$ is a quasi order (also noted qo) if $\leq$ is a quasi ordering over $A$ (and similarly with po, wqo, etc.).

**Example 1.2** (Basic WQOs). The set of nonnegative integers $(\mathbb{N}, \leq)$ is a wqo. Note that it is linear and partial. Given a set $A$, $(A, =)$ is always a po; it is a wqo iff $A$ is finite. (See Exercise 1.1 for more examples of qos and wqos.)
Chapter 1. Basics of WQOs and Applications

Definition 1.4 (wqo.3). A qo \((A, \leq)\) is a wqo iff

1. there are no infinite strictly decreasing sequences \(x_0 > x_1 > x_2 > \cdots\) in \(A\) — i.e., \((A, \leq)\) is well founded —, and

2. there are no infinite sets \(\{x_0, x_1, x_2, \ldots\}\) of mutually incomparable elements in \(A\) — i.e., \((A, \leq)\) has no infinite antichains.

The equivalence between these characterizations is quite useful; see Exercise 1.2 and the following:

Example 1.5. The qos \((\mathbb{Z}, \leq)\) and \((\mathbb{Q}, \leq)\) are not well-founded. The set of positive natural numbers \(\mathbb{N}_+\) ordered by divisibility “|” has infinite antichains, e.g. the set of primes. The set of finite sequences \(\Sigma^*\) ordered lexicographically is not well-founded. None of these examples is wqo.

Regarding the equivalence of (wqo.1), (wqo.2), and (wqo.3), it is clear that (wqo.2) implies (wqo.1), which in turn implies (wqo.3). In order to prove that (wqo.3) implies (wqo.2), we use the Infinite Ramsey Theorem. Assume \((x_i)_{i \in \mathbb{N}}\) is an infinite sequence over \((A, \leq)\), which is a wqo according to (wqo.3). We consider the complete graph over \(\mathbb{N}\) and color every edge \(\{i, j\}\) (where \(i < j\)) with one of three colors. The edge is red when \(x_i \leq x_j\) (up), it is blue when \(x_i > x_j\) (strictly down), and it is green when \(x_i \not\leq x_j \not\leq x_i\) (incomparable). The Infinite Ramsey Theorem shows that there exists an infinite subset \(I \subseteq \mathbb{N}\) of indexes such that every edge \(\{i, j\}\) over \(I\) has the same color. In effect, \(I\) yields an infinite subsequence \((x_i)_{i \in I}\) of \((x_i)_{i \in \mathbb{N}}\). If the subsequence has all its edges red, then we have exhibited an infinite increasing sequence. Since these are not allowed by (wqo.3), the single color for the edges of \(I\) must be red. Hence the original sequence has a infinite increasing subsequence: \((A, \leq)\) satisfies (wqo.2).

1.1.2 Upward-closed Subsets of wqos

Let \((A, \leq)\) be a quasi-ordering. The upward-closure \(\uparrow B\) of some \(B \subseteq A\) is defined as \(\{x \in A \mid x \geq y \text{ for some } y \in B\}\). When \(B = \uparrow B\), we say that \(B\) is upward-closed; the downward-closure \(\downarrow B\) of \(B\) and the notion of downward-closed sets are defined symmetrically.

Definition 1.6 (wqo.4). A qo \((A, \leq)\) is a wqo iff any increasing sequence \(U_0 \subseteq U_1 \subseteq U_2 \subseteq \cdots\) of upward-closed subsets of \(A\) eventually stabilize, i.e., \(\bigcup_{i \in \mathbb{N}} U_i\) is \(U_k = U_{k+1} = U_{k+2} = \ldots\) for some \(k\).

¹See Exercise 1.3 for an elementary proof that does not use Ramsey’s Theorem.
1.1. Well Quasi Orderings

This characterization is sometimes expressed by saying that upward-closed sets satisfy the Ascending Chain Condition. See Exercise 1.5 for the equivalence of (wqo.4) with the other characterizations.

Upward- and downward-closed sets are important algorithmic tools: they are subsets of $A$ that can be finitely represented and handled. The simplest generic representation is by minimal elements:

**Lemma 1.7 (Finite Basis Property).** Let $(A, \leq)$ be a wqo. Any upward-closed $U \subseteq A$ can be written under the form $U = \uparrow \{x_1, \ldots, x_n\}$ for some $x_1, \ldots, x_n \in A$, i.e., as the upward-closure of finitely many elements.

(See Exercise 1.6 for a proof.) One can see how, using this representation, the comparison of possibly infinite (but upward-closed) sets can be reduced to finitely many comparisons of elements.

The complement of a downward-closed set $D$ is upward-closed. Hence downward-closed subsets of a wqo can be characterized by so-called excluded minors.

**Example 1.10 (Subword ordering).** We use $\varepsilon$ to denote the empty sequence. Over $(\Sigma, \preceq)$, where $\Sigma = \{a, b, c\}$ is a 3-letter alphabet and where different letters are incomparable, the word $abb$ is a subword of $cabcab$, as witnessed by the underlined letters, and written $abb \preceq_\ast cabcab$. On the other hand $bba \not\preceq_\ast cabcab$. Over $(\mathbb{N}, \leq)$, examples are $\varepsilon \preceq_\ast 4\cdot1\cdot3 \preceq_\ast 1\cdot5\cdot0\cdot3\cdot0\cdot0$ and $4\cdot1\cdot3 \not\preceq_\ast 1\cdot5\cdot0\cdot3\cdot0\cdot0$. Over $(\mathbb{N}^2, \leq_\chi)$, one checks that $\binom{9}{1} \cdot \binom{7}{0} \cdot \binom{9}{0} \not\preceq_\ast \binom{6}{0} \cdot \binom{9}{1} \cdot \binom{9}{0} \cdot \binom{7}{0} \cdot \binom{9}{0} \cdot \binom{7}{0} \cdot \binom{7}{0} \cdot \binom{8}{0} \cdot \binom{7}{0} \cdot \binom{6}{0}$. 

1.1.3 Constructing wqos

There are several well-known ways of building new wqos out of simpler ones.

We already mention how the product $\prod_{i=1}^m (A_i, \leq_i)$ of finitely many wqos is a wqo (see Exercise 1.2).

**Lemma 1.8 (Dickson’s Lemma).** Let $(A, \leq_A)$ and $(B, \leq_B)$ be two wqos. Then $(A \times B, \leq_{A \times B})$ is a wqo.

There is a more general way of relating tuples of different lengths, which are then better understood as finite sequences over $A$. These can be well-quasi-ordered thanks to a fundamental result by G. Higman:

**Lemma 1.9 (Higman’s Lemma).** Let $(A, \preceq)$ be a wqo. Then $(A^*, \preceq_\ast)$ is a wqo.

See Exercise 1.10 for a proof; here the sequence extension $A^*$ is the set of all finite sequences over $A$, and these sequences are ordered via the subword embedding:

$$(a_1 \cdots a_n) \preceq_\ast (b_1 \cdots b_m) \iff \exists i_1 < i_2 < \cdots < i_n \leq m \text{ s.t. } a_i \leq b_{i_1} \land \cdots \land a_n \leq b_{i_n}. \quad (1.1)$$
It is also possible to order finite and infinite subsets of a wqo in several different ways, see Exercise 1.13.

Higman’s original lemma was actually more general and handled homeomorphisms between finite trees with fixed arities, but this was extended by Kruskal to finite trees with variadic labels:

**Theorem 1.11 (Kruskal’s Tree Theorem).** The set $T(A)$ of finite trees node-labeled from a wqo $(A, \leq)$ and partially ordered by homeomorphic embeddings is a wqo.

(See Exercise 1.15 for the definition of homeomorphic embeddings and a proof of Kruskal’s Theorem.)

Finally, a further generalization of Kruskal’s Tree Theorem exists for graphs:

**Theorem 1.12 (Robertson and Seymour’s Graph-Minor Theorem).** The set of (finite undirected) graphs node-labeled from a wqo $(A, \leq)$ and ordered by the graph-minor relation is a wqo.

### 1.2 Well-Structured Transition Systems

In the field of algorithmic verification of program correctness, wqos figure prominently in well-structured transition systems (WSTS). These are transition system $(S, \to)$, where $S$ is a set of states and $\to \subseteq S \times S$ is a transition relation, further endowed with a wqo $\leq \subseteq S \times S$ that satisfies a compatibility condition:

$$s \to s' \land s \leq t \implies \exists t' \geq s', t \to t'. \quad \text{(compatibility)}$$

Put together, this defines a WSTS $S = (S, \to, \leq)$. In other words, the states of $S$ are well quasi ordered in a way such that “larger” states can simulate the behaviour of “smaller” states.

Several variants of the basic WSTS notion exist (backward compatibility, strict compatibility, …) and we shall mention some of them in exercises 1.16 to 1.19.

**Example 1.13.** A $d$-dimensional vector addition system with states (VASS) is a finite-state system that manipulates $d$ counters with only increment and decrement operations. Formally, it is a tuple $V = (Q, \delta, q_0, x_0)$ where $Q$ is a finite set of states, $\delta \subseteq Q \times \mathbb{Z}^d \times Q$ is a finite set of translations, $q_0$ in $Q$ is an initial state, and $x_0$ in $\mathbb{N}^d$ describes the initial counter contents.

The semantics of a VASS define a transition system $(Q \times \mathbb{N}^d, \to)$ where a transition $\to$ holds between two configurations $(q, x)$ and $(q', x')$ if and only if there exists a translation $(q, a, q')$ in $\delta$ with $x' = x + a$; note that this transition requires $x + a$ non negative.

We can check that this transition system is a WSTS for the product ordering $\leq$ over $Q \times \mathbb{N}^d$, i.e. for $(q, x) \leq (q', x')$ iff $q = q'$ and $x(j) = x'(j)$ for all $j = 1, \ldots, d$. Indeed, whenever $(q, x) \to (q', x')$ and $x \leq y$, then there exists $(q, a, q')$ in $\delta$ s.t. $x' = x + a$, and $y' = y + a \geq x + a \geq 0$, thus $(q, y) \to (q', y')$. 
1.2.1 Termination

A transition system $\langle S, \rightarrow \rangle$ terminates from some state $s_0$ in $S$, if every transition sequence $s_0 \rightarrow s_1 \rightarrow \cdots$ is finite. This gives rise to the following, generally undecidable, problem:

**[Term]** Termination

*instance:* A transition system $\langle S, \rightarrow \rangle$ and a state $s_0$ in $S$.

*question:* Does $\langle S, \rightarrow \rangle$ terminate from $s_0$?

In a WSTS, non-termination can be witnessed by increasing pairs in a finite run:

**Lemma 1.14.** Let $S = \langle S, \rightarrow, \leq \rangle$ be a WSTS and $s_0$ be a state in $S$. Then $S$ has an infinite run starting from $s_0$ iff $S$ has a run $s_0 \rightarrow s_1 \rightarrow \cdots \rightarrow s_j$ with $s_i \leq s_j$ for some $0 \leq i < j$.

*Proof.* The direct implication follows from [wqo.1] applied to the infinite run $s_0 \rightarrow s_1 \rightarrow \cdots$. The converse implication follows from repeated applications of the compatibility condition to build an infinite run: first there exists $s_{j+1} \geq s_{i+1}$ s.t. $s_j \rightarrow s_{j+1}$, and so on and so forth. □

There is therefore a simple procedure to decide [Term], pending some effectiveness conditions: in a transition system $\langle S, \rightarrow \rangle$, define the **successor set**

$$Post(s) \overset{\text{def}}{=} \{s' \in S \mid s \rightarrow s'\}$$

of any $s$ in $S$. A transition system is **image-finite** if $Post(s)$ is finite for all $s$ in $S$. It is **Post-effective** if these elements can effectively be computed from $s$.

**Proposition 1.15 (Decidability of Termination for WSTSs).** Let $S = \langle S, \rightarrow, \leq \rangle$ be a WSTS and $s_0$ be a state in $S$. If $S$ is image-finite, Post-effective, and $\leq$ is decidable, then termination of $S$ from $s_0$ is also decidable.

*Proof.* The algorithm consists of two semi-algorithms. The first one attempts to prove termination and builds a **reachability tree** starting from $s_0$; if $S$ terminates from $s_0$, then every branch of this tree will be finite, and since $S$ is image-finite this tree is also finitely branching, hence finite overall by König’s Lemma. The second one attempts to prove non-termination, and looks nondeterministically for a finite witness matching Lemma 1.14. □

1.2.2 Coverability

The second decision problem we consider on WSTSs is also of great importance, as it encodes safety checking: can an error situation occur in the system?

**[Cover]** Coverability

*instance:* A transition system $\langle S, \rightarrow \rangle$, a qo $\langle S, \leq \rangle$, and two states $s, t$ in $S$.

*question:* Is $t$ coverable from $s$, i.e. is there a run $s = s_0 \rightarrow s_1 \rightarrow \cdots \rightarrow s_n \geq t$?
Chapter 1. Basics of WQOs and Applications

In the particular case of a WSTS over state space \( Q \times A \) for some finite set of control states \( Q \) and some wqo domain \((A, \leq_A)\), the Control-state Reachability Problem asks whether some input state \( q \) can be reached, regardless of the associated data value. This immediately reduces to coverability of the finitely many minimal elements of \( \{q\} \times A \) for the product ordering over \( Q \times A \), i.e. \((q, x) \leq (q', x')\) iff \( q = q' \) and \( x \leq_A x' \).

The decidability of Cover for WSTS uses a set-saturation method, whose termination relies on (wqo.4). This particular algorithm is called the backward coverability algorithm, because it essentially computes all the states \( s \) s.t. \( s \rightarrow^* t' \geq t \). For a set of states \( I \subseteq S \), define its predecessor set

\[
\text{Pre}(I) \overset{\text{def}}{=} \{ s \in S \mid \exists s' \in I, s \rightarrow s' \}.
\]

The backward analysis computes the limit \( \text{Pre}^*(I) \) of the sequence

\[
I = I_0 \subseteq I_1 \subseteq \cdots \text{ where } I_{n+1} \overset{\text{def}}{=} I_n \cup \text{Pre}(I_n) \,.
\]

There is no reason for (1.4) to converge in general, but for WSTs, this can be solved when \( I \) is upward-closed:

**Lemma 1.16.** If \( I \subseteq S \) is an upward-closed set of states, then \( \text{Pre}(I) \) is upward-closed.

**Proof.** Assume \( s \in \text{Pre}(I) \). Then \( s \rightarrow t \) for some \( t \in I \). By compatibility of \( S \), if \( s' \geq s \), then \( s' \rightarrow t' \) for some \( t' \geq t \). Thus \( t' \in I \) and \( s' \in \text{Pre}(I) \).

A corollary is that sequence (1.4) stabilizes to \( \text{Pre}^*(I) \) after a finite amount of time thanks to (wqo.4). The missing ingredient is an effectiveness one: a WSTS has effective pred-basis if there exists an algorithm accepting any state \( s \in S \) and returning \( \text{pb}(s) \), a finite basis of \( \uparrow\text{Pre}(\uparrow\{s\}) \).

**Proposition 1.17** (Decidability of Coverability for WSTs). Let \( S = \langle S, \rightarrow, \leq \rangle \) be a WSTS and \( s, t \) be two states in \( S \). If \( S \) has effective pred-basis and decidable \( \leq \), then coverability of \( t \) from \( s \) in \( S \) is also decidable.

**Proof.** Compute a finite basis \( B \) for \( \text{Pre}^*(\uparrow\{t\}) \) using sequence (1.4) and calls to \( \text{pb} \), and test whether \( s \geq b \) for some \( b \) in \( B \).

Exercises 1.17 and 1.19 present variants of this algorithm for different notions of compatibility.

---

²This definition is slightly more demanding than required, in order to accommodate for weaker notions of compatibility.
1.3. Examples of Applications

Let us present three applications of wqos in three different areas: one is quite generic and is concerned with proving program termination (Section 1.3.1). The other two are more specialized: we present applications to relevance logic (Section 1.3.2) and vector addition systems (Section 1.3.3).

1.3.1 Program Termination

**Bad Sequences and Termination.** Recall from Definition 1.1 that one of the characterizations for $(A, \leq)$ to be a wqo is that every infinite sequence $a_0, a_1, \ldots$ over $A$ contains an increasing pair $a_{i_1} \leq a_{i_2}$ for some $i_1 < i_2$. We say that (finite or infinite) sequences with an increasing pair $a_{i_1} \leq a_{i_2}$ are good sequences, and call bad a sequence where no such increasing pair can be found. Therefore every infinite sequence over the wqo $A$ is good, i.e., bad sequences over $A$ are finite.

In order to see how bad sequences are related to termination, consider the *simple* program presented in Figure 2.1. We can check that every run of simple terminates, this for any choice of initial values $(a_0, b_0)$ of $a$ and $b$. Indeed, we can consider any sequence

$$\langle a_0, b_0, c_0 \rangle, \ldots, \langle a_j, b_j, c_j \rangle, \ldots$$

(1.5)

of successive configurations of simple, project away its third component, yielding a sequence

$$\langle a_0, b_0 \rangle, \ldots, \langle a_j, b_j \rangle, \ldots$$

(1.6)

and look at any factor $\langle a_{i_1}, b_{i_1} \rangle, \ldots, \langle a_{i_2}, b_{i_2} \rangle$ inside it:

- either only the first transition $l$ is ever fired between steps $i_1$ and $i_2$, in which case $a_{i_2} < a_{i_1}$,
- or the second transition $r$ was fired at least once, in which case $b_{i_2} < b_{i_1}$.

Thus $\langle a_{i_1}, b_{i_1} \rangle \not\leq \langle a_{i_2}, b_{i_2} \rangle$, which means that (1.6) is a bad sequence over $(\mathbb{N}^2, \leq)$, and is therefore a finite sequence. Consequently, (1.5) is also finite, which means that simple always terminates.
RANKING FUNCTIONS. Program termination proofs essentially establish that the program’s transition relation $R$ is well-founded (aka Noetherian), i.e. that there does not exist an infinite sequence of program configurations $x_0 R x_1 R x_2 R \cdots$. In the case of the integer program \textsc{simple}, this relation is included in $\mathbb{Z}^3 \times \mathbb{Z}^3$ and can be easily read from the program:

$$\langle a, b, c \rangle R \langle a', b', c' \rangle \text{ iff } a > 0 \land b > 0 \land (\langle a' = a - 1 \land b' = b \land c' = 2c \rangle \lor \langle a' = 2c \land b' = b - 1 \land c' = 1 \rangle).$$

(1.7)

The classical, “monolithic” way of proving well-foundedness is to exhibit a ranking function $\rho$ from the set of program configurations $x_0, x_1, \ldots$ into a well-founded order $(O, \leq)$ such that

$$R \subseteq \{ (x_i, x_j) \mid \rho(x_i) > \rho(x_j) \}.$$  

(1.8)

Then $R$ is well-founded, otherwise we could exhibit an infinite decreasing sequence in $(O, \leq)$.

This is roughly what we did in (1.6), by projecting away the third component and using $\mathbb{N}^2$ as codomain; this does not satisfy (1.8) for the product ordering $(\mathbb{N}^2, \leq)$, but it does satisfy it for the lexicographic ordering $(\mathbb{N}^2, \leq_{\text{lex}})$. Equivalently, one could define $\rho : \mathbb{Z}^3 \to \omega^2$ by $\rho(a, b, c) = \omega \cdot b + a$ if $a, b \geq 0$ and $\rho(a, b, c) = 0$ otherwise.

However our argument with (1.6) was rather to use bad sequences: we rather require $\rho$ to have a wqo $(A, \leq)$ as co-domain, and check that the transitive closure $R^+$ of $R$ verifies

$$R^+ \subseteq \{ (x_i, x_j) \mid \rho(x_i) \not< \rho(x_j) \}$$

(1.9)

instead of (1.8). Again, (1.9) proves $R$ to be well-founded, as otherwise we could exhibit an infinite bad sequence in $(A, \leq)$.

Proving termination with these methods is done in two steps: first find a ranking function, then check that it yields termination through (1.8) for well-founded orders or (1.9) for wqos. As it turns out that finding an adequate ranking function is often the hardest part, this second option might be preferable.

TRANSITION INVARIANTS. A generalization of these schemes with a simpler search for ranking functions is provided by disjunctive termination arguments: in order to prove that $R$ is well-founded, one rather exhibits a finite set of well-founded relations $T_1, \ldots, T_k$ and prove that

$$R^+ \subseteq T_1 \cup \cdots \cup T_k.$$  

(1.10)

Each of the $T_j$, $1 \leq j \leq k$, is proved well-founded through a ranking function $\rho_j$, but these functions might be considerably simpler than a single, monolithic ranking function for $R$. In the case of \textsc{simple}, choosing

$$T_1 = \{ (\langle a, b, c \rangle, \langle a', b', c' \rangle) \mid a > 0 \land a' < a \}$$

(1.11)

$$T_2 = \{ (\langle a, b, c \rangle, \langle a', b', c' \rangle) \mid b > 0 \land b' < b \}$$

(1.12)
1.3. Examples of Applications

fits, their well-foundedness being immediate by projecting on the first (resp. second) component.

Let us prove the well-foundedness of $R$ when each of the $T_j$ is proven well-founded thanks to a ranking function $\rho_j$ into some wqo $\langle A_j, \leq_j \rangle$ (see Exercise 1.22 for a generic proof that only requires each $T_j$ to be well-founded). Then with a sequence

$$x_0, x_1, \ldots$$

(1.13)

of program configurations one can associate the sequence of tuples

$$\langle \rho_1(x_0), \ldots, \rho_k(x_0) \rangle, \langle \rho_1(x_1), \ldots, \rho_k(x_1) \rangle, \ldots$$

(1.14)

in $A_1 \times \cdots \times A_k$, the latter being a wqo for the product ordering by Dickson’s Lemma. Since for any indices $i_1 < i_2$, $(x_{i_1}, x_{i_2}) \in R^+$ is in some $T_j$ for some $1 \leq j \leq k$, we have $\rho_j(x_{i_1}) \not\leq_j \rho_j(x_{i_2})$ by definition of a ranking function. Therefore the sequence of tuples is bad for the product ordering and thus finite, and the program terminates.

Different strategies can be used in practice to find a disjunctive termination invariant of the form (1.10). One that works well in the example of simple is to use the structure of the program relation $R$: if $R$ can be decomposed as a union $R_1 \cup \cdots \cup R_k$, then applying rank function synthesis to each $R_j$, thereby obtaining a well-founded overapproximation $\text{wf}(R_j) \supseteq R_j$, provides an initial candidate termination argument

$$\text{wf}(R_1) \cup \cdots \cup \text{wf}(R_k).$$

(1.15)

Applying this idea to simple, we see that $R$ in (1.7) is the union of

$$R_1 = \left\{ \langle (a, b, c), \langle a', b', c' \rangle \rangle \mid a > 0 \land b > 0 \land a' = a - 1 \land b' = b \land c' = 2c \right\}$$

(1.16)

$$R_2 = \left\{ \langle (a, b, c), \langle a', b', c' \rangle \rangle \mid a > 0 \land b > 0 \land a' = 2c \land b' = b - 1 \land c' = 1 \right\},$$

(1.17)

which can be overapproximated by $T_1$ and $T_2$ in (1.11) and (1.12).

It remains to check that (1.10) holds. If it does not, we can iterate the previous approximation technique, computing an overapproximation $\text{wf}(\text{wf}(R_{j_1}) \circledast R_{j_2})$ of the composition of $R_{j_1}$ with $R_{j_2}$, then $\text{wf}(\text{wf}(\text{wf}(R_{j_1}) \circledast R_{j_2}) \circledast R_{j_3})$ etc. until their union reaches a fixpoint or proves termination.

1.3.2 Relevance Logic

Relevance logics provide different semantics of implication, where a fact $B$ is said to follow from $A$, written “$A \triangleright B$”, only if $A$ is actually relevant in the deduction of $B$. This excludes for instance $A \triangleright (B \triangleright A)$, $(A \land \neg A) \triangleright B$, etc.

We focus here on the implicative fragment $\mathbf{R}_{\subseteq}$ of relevance logic, which can be defined through a substructural sequent calculus in Gentzen’s style. We use
upper-case letters $A, B, C, \ldots$ for formulæ and $\alpha, \beta, \gamma, \ldots$ for possibly empty sequences of formulæ; a sequent is an expression $\alpha \vdash A$. The rules for $\mathcal{R}_\supset$ are:

\[
\begin{array}{ll}
\begin{array}{l}
A \vdash A \quad \text{(Ax)}
\end{array} & \\
\begin{array}{lll}
\alpha \vdash A & \beta A \vdash B & \text{(Cut)}
\end{array}
\end{array}
\]

\[
\begin{array}{ll}
\frac{\alpha \beta B \vdash C}{\alpha A \beta A \alpha \vdash C} & \text{(Ex)}
\end{array}
\]

\[
\begin{array}{ll}
\alpha A A \vdash B & \text{(Con)}
\end{array}
\]

\[
\begin{array}{ll}
\frac{\alpha \vdash A & \beta B \vdash C}{\alpha \beta (A \supset B) \vdash C} & \text{($\supset_l$)}
\end{array}
\]

\[
\begin{array}{ll}
\frac{\alpha \beta A \vdash B}{\alpha \vdash A \supset B} & \text{($\supset_r$)}
\end{array}
\]

where (Ex) and (Con) are the structural rules of exchange and contraction. Note that the weakening rule (W) of propositional calculus is missing: otherwise we would have for instance the undesired derivation

\[
\begin{array}{ll}
\frac{\text{Ax}}{A \vdash A} & \text{(W)}
\end{array}
\]

\[
\begin{array}{ll}
\frac{\text{Dr}_l}{AB \vdash A} & \text{(Dr}_l)
\end{array}
\]

\[
\begin{array}{ll}
\frac{A \vdash B \supset A}{\vdash A \supset (B \supset A)} & \text{(Dr}_r)
\end{array}
\]

There are two important simplifications possible in this system: the first one is to redefine $\alpha, \beta, \ldots$ to be multisets of formulæ, which renders (Ex) useless; thus juxtaposition in (Ax–R) should be interpreted as multiset union.

The second one is cut elimination, i.e. any sequent derivable in $\mathcal{R}_\supset$ has a derivation that does not use (Cut). This can be seen by the usual arguments, where cuts are progressively applied to “smaller” formulæ, thanks to a case analysis. For instance,

\[
\begin{array}{ll}
\vdots & \vdots \\
\gamma A \vdash B & \alpha \vdash A \quad \beta B \vdash C \\
\frac{\gamma \vdash A \supset B}{\alpha \beta(\gamma \vdash A \supset B) \vdash C} & \text{(Cut)}
\end{array}
\]

can be rewritten into

\[
\begin{array}{ll}
\vdots & \\
\gamma A \vdash B & \alpha \vdash A \quad \\
\frac{\gamma A \vdash B}{\alpha \gamma \vdash B} & \text{Cut} \\
\alpha \gamma \vdash B & \beta B \vdash C \\
\frac{\alpha \beta \gamma \vdash C}{\text{Cut}}
\end{array}
\]

A consequence of cut elimination is that $\mathcal{R}_\supset$ enjoys the subformula property:

**Lemma 1.18** (Subformula Property). If $\alpha \vdash A$ is a derivable sequent in $\mathcal{R}_\supset$, then there is a cut-free derivation of $\alpha \vdash A$ where every formula appearing in any sequent is a subformula of some formula of $\alpha A$. 
1.3. Examples of Applications

The Decision Problem we are interested in solving is whether a formula $A$ is a theorem of $R$; it is readily generalized to whether a sequent $\alpha \vdash A$ is derivable using ($\text{Ax}$$\rightarrow$$R$).

[RI] Relevant Implication

instance: A formula $A$ of $R$.

question: Can the sequent $\vdash A$ be derived in $R$?

A natural idea to pursue for deciding RI is to build a proof search tree with nodes labeled by sequents, and reversing rule applications from the root $\vdash A$ until only axioms are found as leaves. An issue with this idea is that the tree grows to an unbounded size, due in particular to contractions. See Exercise 1.25 for an algorithm that builds on this idea.

We reduce here RI to a WSTS coverability problem. Given $A$, we want to construct a WSTS $S = \langle S, \rightarrow, \leq \rangle$, a target state $t$ of $S$, and an initial state $s$ in $S$ s.t. $t$ can be covered in $S$ from $s$ if and only if $A$ is a theorem of $R$.

Write $\text{Sub}(A)$ for its finite set of subformulas. Then, by the Subformula Property, any sequent $\vdash B$ that derives $A$ in a cut-free proof can be seen as an element of $\text{Seq}(A) \triangleq N^{\text{Sub}(A)} \times \text{Sub}(A)$; we let

$$S \triangleq P_f(\text{Seq}(A))$$

be the set of finite subsets of $\text{Seq}(A)$.

Given a finite set $s'$ of sequents, we say that

$$s' \rightarrow s' \cup \{ \alpha \vdash B \}$$

if some rule among ($\text{Ax}$$\rightarrow$$R$) ($\text{Cut}$ excepted) can employ some premise(s) in $s'$ to derive the sequent $\alpha \vdash B$.

For a multiset $\alpha$, define its multiset support $\sigma(\alpha)$ as its underlying set of elements $\sigma(\alpha) = \{ B \mid \alpha(B) > 0 \}$. We define the contraction $qo \ll$ over sequents by $\alpha \vdash B \ll \alpha' \vdash B'$ iff $\alpha \vdash B$ can be obtained from $\alpha' \vdash B'$ by some finite, possibly null, number of contractions. Over $\text{Seq}(A)$, this is equivalent to having $\alpha \leq \alpha'$ (for the product ordering over $N^{\text{Sub}(A)}$), $\sigma(\alpha) = \sigma(\alpha')$, and $B = B'$; $\ll$ over $\text{Seq}(A)$ is thus defined as a product ordering between the three wqos ($N^{\text{Sub}(A)}, \leq$), $(P(\text{Sub}(A)), =)$, and $(\text{Sub}(A), =)$, and therefore by Dickson’s Lemma:

Lemma 1.19 (Kripke’s Lemma). The $qo$ ($\text{Seq}(A), \ll$) is a wqo.

Then, by Exercise 1.13, the $qo$ ($S, \leq$), where $\leq$ is Hoare’s ordering applied to $\ll$, is a wqo, and we easily see that $S = \langle S, \rightarrow, \leq \rangle$ is a WSTS with effective predbasis and a decidable ordering (see Exercise 1.24), thus the coverability problem for

$$s \triangleq \{ B \vdash B \mid B \in \text{Sub}(A) \}$$

is decidable by Proposition 1.17.
It remains to check that coverability of \( \langle S, s, t \rangle \) is indeed equivalent to derivability of \( \vdash A \). Clearly, if \( s = s_0 \rightarrow s_1 \rightarrow \cdots \rightarrow s_n \), then any sequent appearing in any \( s_i \) along this run is derivable in \( R_S \), and if \( t \leq s_n \)—which is equivalent to the existence of a sequent \( \alpha \vdash B \) in \( s_n \), s.t. \( A \ll \alpha \vdash B \), which by definition of \( \ll \) is equivalent to \( \sigma(\alpha) = \emptyset \) and \( A = B \), i.e. to \( \vdash A \) being in \( s_n \)—, then \( A \) is indeed a theorem of \( R_S \). Conversely, if \( \vdash A \) is derivable by a cut-free proof in \( R_S \), then we can reconstruct a run in \( S \) by a breadth-first visit starting from the leaves of the proof tree, which starts from the set \( s_0 \subseteq s \) of leaves of the proof tree, applies \( \rightarrow \) along the rules (Ax–R) of the proof tree, and ends at the root of the proof tree with a set \( s' \) of sequents that includes \( \vdash A \). Finally, by compatibility of \( S \), since \( s_0 \leq s \), there exists a run \( s \rightarrow \cdots \rightarrow s'' \) such that \( t = \{ \vdash A \} \subseteq s' \leq s'' \), proving that \( t \) is indeed coverable from \( s \) in \( S \).

1.3.3 Karp & Miller Trees

Vector Addition Systems (VAS) are systems where \( d \) counters evolve by non-deterministically applying \( d \)-dimensional translations from a fixed set, i.e. they are single-state VASSs. They can be seen as an abstract presentation of Petri nets, and are thus widely used to model concurrent systems, reactive systems with resources, etc. They also provide an example of systems for which WSTS algorithms work especially well.

Formally, a \( d \)-dimensional VAS is a pair \( V = (x_0, A) \) where \( x_0 \) is an initial configuration in \( \mathbb{N}^d \) and \( A \) is a finite set of translations in \( \mathbb{Z}^d \). A translation \( a \) in \( A \) can be applied to a configuration \( x \) in \( \mathbb{N}^d \) if \( x' = x + a \) is in \( \mathbb{N}^d \), i.e. non-negative. The resulting configuration is then \( x' \), and we write \( x \xrightarrow{a} V x' \). A \( d \)-dimensional VAS \( V \) clearly defines a WSTS \( \langle \mathbb{N}^d, \rightarrow, \leq \rangle \) where \( \rightarrow = \bigcup_{a \in A} \xrightarrow{a} V \) and \( \leq \) is the product ordering over \( \mathbb{N}^d \). A configuration \( x \) is reachable, denoted \( x \in \text{Reach}(V) \), if there exists a sequence

\[
\begin{align*}
x_0 & \xrightarrow{a_1} x_1 \\
& \xrightarrow{a_2} x_2 \\
& \vdots \\
& \xrightarrow{a_n} x_n = x.
\end{align*}
\]

That reachability is decidable for VASs is a major result of computer science but we are concerned here with computing a covering of the reachability set.

Coverings. In order to define what is a “covering”, we consider the completion \( \mathbb{N}_\omega = \mathbb{N} \cup \{\omega\} \) of \( \mathbb{N} \) and equip it with the obvious ordering. Tuples \( y \in \mathbb{N}^d_\omega \), called \( \omega \)-markings, are ordered with the product ordering. Note that \( \mathbb{N}_\omega \) is a wqo, and thus \( \mathbb{N}^d_\omega \) as well by Dickson’s Lemma.

While \( \omega \)-markings are not proper configurations, it is convenient to extend the notion of steps and write \( y \xrightarrow{a} y' \) when \( y' = y + a \) (assuming \( n + \omega = \omega + n = \omega \) for all \( n \)).

**Definition 1.20 (Covering).** Let \( V \) be a \( d \)-dimensional VAS. A set \( C \subseteq \mathbb{N}^d_\omega \) of \( \omega \)-markings is a covering for \( V \) if
1. for any $x \in \text{Reach}(V)$, $C$ contains some $y$ with $x \leq y$, and

2. any $y \in C$ is in the adherence of the reachability set, i.e. $y = \lim_{i=1,2,...} x_i$ for some infinite sequence of configurations $x_1, x_2, \ldots$ in $\text{Reach}(V)$.

Hence a covering is a rather precise approximation of the reachability set (precisely, the adherence of its downward-closure). A fundamental result is that finite coverings always exist and are computable. This entails several decidability results, e.g. whether a counter value remains bounded throughout all the possible runs.

The Karp & Miller tree constructs a particular covering of $V$. Formally, this tree has nodes labeled with $\omega$-markings in $\mathbb{N}_\omega^d$ and edges labeled with translations in $A$. The root $s_0$ is labeled with $x_0$ and the tree is grown in the following way:

Assume a node $s$ of the tree is labeled with some $y$ and let $y_0, y_1, \ldots y_n$ be the sequence of labels on the path from the root $s_0$ to $s$, with $x_0 = y_0$ and $y_n = y$. For any translation $a \in A$ such that there is a step $y \xrightarrow{a} y'$, we consider whether to grow the tree by adding a child node $s'$ to $s$ with an $a$-labeled edge from $s$ to $s'$:

1. If $y' \leq y_i$ for one of the $y_i$'s on the path from $s_0$ to $s$, we do not add $s'$ (the branch ends).

2. Otherwise, if $y' > y_i$ for some $i = 0, \ldots, n$, we build $y''$ from $y'$ by setting, for all $j = 1, \ldots, d$,

$$y''(j) \overset{\text{def}}{=} \begin{cases} \omega & \text{if } y'(j) > y_i(j) \\ y'(j) & \text{otherwise.} \end{cases}$$

Formally, $y''$ can be thought as "$y_i + \omega \cdot (y' - y_i)$." We add $s'$, the edge from $s$ to $s'$, and we label $s'$ with $y''$.

3. Otherwise, $y'$ is not comparable with any $y_i$: we simply add the edge and label $s'$ with $y'$.
Chapter 1. Basics of WQOs and Applications

See Figure 1.2 for an example of tree constructed by this procedure.

**Theorem 1.21.** The above algorithm terminates and the set of labels in the Karp & Miller tree is a covering for \( V \).

**Proof of termination.** First observe that the tree is finitely branching (a node has at most \(|A|\) children), thus by König’s Lemma the tree can only be infinite by having an infinite branch. Assume, for the sake of contradiction, that there is such an infinite branch labeled by some \( y_0, y_1, \ldots \) with \( i_0 < i_1 < \cdots \). Any successive pair \( y_{i_k} \leq y_{i_{k+1}} \) requires \( y_{i_{k+1}} \) to be inserted at step \( 2 \) of the algorithm, hence \( y_{i_{k+1}} \) has more \( \omega \)-components than \( y_{i_k} \). Finally, since an \( \omega \)-marking has at most \( d \) \( \omega \)-components, this extracted sequence is of length at most \( d + 1 \) and cannot be infinite.

We leave the second part of the proof as Exercise 1.27.

**Exercises**

**Exercise 1.1** (Examples of qos). Among the following quasi orders, which ones are partial orders? Are they total? Well-founded? Wqo?

1. the natural numbers \((\mathbb{N}, \leq)\), the integers \((\mathbb{Z}, \leq)\), the positive reals \((\mathbb{R}^+, \leq)\);

2. the natural numbers \((\mathbb{N}, |)\) where \( a | b \) means that \( a \) divides \( b \);

3. given a linearly ordered finite alphabet \( \Sigma \), the set of finite sequences \( \Sigma^* \) with prefix ordering \( \preceq_{\text{pref}} \) or lexicographic ordering \( \preceq_{\text{lex}} \);

4. \((\mathcal{P}(\mathbb{N}), \subseteq)\) the subsets of \( \mathbb{N} \) ordered with inclusion;

5. \((\mathcal{P}(\mathbb{N}), \subseteq_S)\) where we use Smyth’s ordering: \( U \subseteq_S V \iff \forall m \in V, \exists n \in U, n \leq m \);

6. \((\mathcal{P}_f(\mathbb{N}), \subseteq)\) and \((\mathcal{P}_f(\mathbb{N}), \subseteq_S)\) where we restrict to finite subsets.

**Exercise 1.2** (Generalized Dickson’s Lemma). If \((A_i, \leq_i)_{i=1, \ldots, m}\) are \( m \) quasi-orderings, their product is \( \prod_{i=1}^m (A_i, \leq_i) = (A, \leq_{\times}) \) given by \( A = A_1 \times \cdots \times A_m \), and

\[
(x_1, \ldots, x_m) \leq_{\times} (x'_1, \ldots, x'_m) \iff x_1 \leq_1 x'_1 \land \cdots \land x_m \leq_m x'_m.
\]

1. Show that \( \prod_{i=1}^m (A_i, \leq_i) \) is well-founded when each \( (A_i, \leq_i) \) is.

2. Show that \( \prod_{i=1}^m (A_i, \leq_i) \) is a wqo when each \( (A_i, \leq_i) \) is.

**Exercise 1.3** (Equivalence of (wqo.1), (wqo.2), and (wqo.3)). Assume that \((A, \leq)\) is a wqo in the sense of Definition 1.1. We want to show that it satisfies Definition 1.3 without invoking Ramsey’s Theorem as was done in Section 1.1.1. For this we follow Erdős et al. (1950).
(1) Consider an infinite sequence \(x_0, x_1, x_2, \ldots\) over \(A\) and write \(M\) for the set \(\{i \in \mathbb{N} \mid x_i \not\leq x_j \text{ for all } j > i\}\). Show that \(M\) is finite.

(2) Conclude and show that \((\text{wqo.1})\) implies \((\text{wqo.2})\).

(3) Prove, using similar ideas, that \((\text{wqo.3})\) implies \((\text{wqo.1})\).

Exercise 1.4 (How many antichains?). Assume that \((A, \leq)\) is countable and well-founded. Show that \((A, \leq)\) is wqo iff the set of its antichains is countable.

Exercise 1.5 (Ascending Chain Condition). Show that \((\text{wqo.4})\) is equivalent with the other definition(s) of wqos.

Exercise 1.6 (Finite Basis Property).

(1) For a qo \((A, \leq)\) and a subset \(U \subseteq A\), we say that \(x\) is a "minimal element of \(U\)" if \(x \in U\) and there is no \(y \in U\) with \(y < x\). Show that every element of a well-founded qo is larger than or equal to a minimal element of the qo.

(2) \((\text{wqo.5})\) Prove that a qo \((A, \leq)\) is a wqo iff every non-empty subset \(U\) of \(A\) contains at least one, and at most finitely many (up to equivalence), minimal elements.

(3) Prove \(\text{Lemma 1.7}\): any upward-closed subset \(U\) of a wqo \((A, \leq)\) can be written under the form \(U = \uparrow \{x_1, \ldots, x_n\}\).

Exercise 1.7 (Linear WQOs).

(1) Prove that a linear ordering is a wqo iff it is well-founded.

(2) \((\text{wqo.6})\) Prove that a qo is a wqo iff all its linearizations are well-founded, where a linearization of \((A, \leq)\) is any linear qo \((A, \preceq)\) with same support set and such that \(x \leq y\) implies \(x \preceq y\) (and such that \(x < y\) implies \(x \preceq y\)). Here one may assume the \(\text{Order-extension principle}\) "every qo has a linearization".

Exercise 1.8 \((\mathbb{Z}^k, \leq_{\text{sparse}})\). We consider the sparser-than ordering. Assume that \(a = (a_1, \ldots, a_k)\) and \(b = (b_1, \ldots, b_k)\) are two tuples in \(\mathbb{Z}^k\), then

\[
a \leq_{\text{sparse}} b \iff \forall i, j \in \{1, \ldots, k\} : (a_i \leq a_j \text{ iff } b_i \leq b_j) \text{ and } (|a_i - a_j| \leq |b_i - b_j|).
\]

Show that \((\mathbb{Z}^k, \leq_{\text{sparse}})\) is a wqo.

Exercise 1.9 (Rado’s Structure). We consider the following set \(R = \{(a, b) \in \mathbb{N}^2 \mid a < b\}\) ordered with

\[
(a, b) \leq_R (a', b') \iff (a = a' \land b \leq b') \lor b < a'.
\]

Show that \((R, \leq_R)\) is a wqo.

Exercise 1.10 (Higman’s Lemma). Recall that for a qo \((A, \leq)\), the set \(A^*\) of finite sequences ("words") over \(A\) can be ordered by the subword embedding \(\leq_s\) defined with \((1.1)\). We shall prove \(\text{Higman’s Lemma}\): \((A^*, \leq_s)\) is wqo \((A, \leq)\) is.
(1) Show that \((A^*, \leq_s)\) is well-founded if \((A, \leq)\) is.

(2) Assume, by way of contradiction, that \((A, \leq)\) is wqo but \((A^*, \leq_s)\) is not. Then there exist some infinite bad sequences over \(A^*\), i.e., sequences of the form \(w_0, w_1, w_2, \ldots\) where \(w_i \not\leq_s w_j\) for all \(i, j \in \mathbb{N}\) s.t. \(i < j\).

Consider all words that can start such an infinite bad sequence, pick a shortest one among them, and call it \(v_0\). Consider now all infinite bad sequences that start with \(v_0\) and, among all words that can appear after the initial \(v_0\), pick a shortest one and call it \(v_1\). Repeat the process and at stage \(k\) pick \(v_k\) as one among the shortest words that can appear after \(v_0, \ldots, v_{k-1}\) inside an infinite bad sequence. Show that this process can be continued forever and that is generates an infinite sequence \(S = v_0, v_1, \ldots\)

(3) Show that \(S\) itself is a bad sequence.

(4) We now write every \(v_i\) under the form \(v_i = a_i u_i\) where \(a_i \in A\) is the first “letter” of \(v_i\) and \(u_i\) is the first strict suffix (this is possible since an infinite bad sequence cannot contain the empty word). We now pick an infinite increasing sequence \(a_{k_0} \leq a_{k_1} \leq a_{k_2} \leq \cdots\) from \((a_i)_{i \in \mathbb{N}}\) (possible since \(A\) is wqo) and we write \(S'\) for the sequence \(u_{k_0}, u_{k_1}, \ldots\) of corresponding suffixes. Show that if \(S'\) is good—i.e., contains an increasing pair—, then \(S\) is good too.

(5) We deduce that \(S'\) must be an infinite bad sequence over \(A^*\). Use this to derive a contradiction (hint: recall the definition of \(v_{i_0}\)).

At this point we conclude that our assumption “\(A\) is wqo but \(A^*\) is not” was contradictory, proving **Higman’s Lemma**

**Exercise 1.11** (Higman’s Lemma for \(\omega\)-sequences). Let \((A, \leq)\) be a wqo. For two infinite words \(v = (x_i)_{i \in \mathbb{N}}\) and \(w = (y_i)_{i \in \mathbb{N}}\) in \(A^\omega\), we let

\[
v \leq^\omega w \iff \left\{ \begin{array}{l}
\text{there are some indexes } n_0 < n_1 < n_2 < \cdots \\
\text{s.t. } x_i \leq y_{n_i} \text{ for all } i \in \mathbb{N}.
\end{array} \right.
\]

(1) We start with the \(\omega\)-sequence extension of \((\mathbb{N}, \leq)\) and consider \(\omega\)-words \(v, w \in \mathbb{N}^\omega\) of natural numbers. We say that an \(\omega\)-word \(v \in \mathbb{N}^\omega\) is **unbounded** if it contains arbitrarily large natural numbers. What can you say about unbounded \(\omega\)-words and \(\leq^\omega\)?

(2) With a bounded \(\omega\)-word \(v \in \mathbb{N}^\omega\), of the form \(v = x_0, x_1, x_2, \ldots\), we associate \(L(v)\), defined as \(L(v) \defeq \lim_{i \to \infty} \sup_{x_i = \lim_{k \to \infty} \max_{i \geq k} x_i} (\text{note that } L(v) \text{ is a finite number since } v \text{ is bounded})\), we let \(M(v)\) be the first index such \(x_i \leq L(v)\) for all \(i \geq M(v)\).

The finite sequence \(\hat{v} \defeq x_0, \ldots, x_{M(v)-1}\) is the shortest prefix of \(v\) such that \(v\) can be written \(v = \hat{v} \bar{v}\) with \(\bar{v}\) an \(\omega\)-length suffix having all its elements bounded by \(L(v)\).

Assume that \(w = y_0, y_1, y_2, \ldots\) is a second bounded \(\omega\)-word and show that

\[
L(v) \leq L(w) \text{ implies } \hat{v} \leq^\omega \bar{w},
\]

\[
(L(v) \leq L(w) \land \hat{v} \leq_s \bar{w}) \text{ implies } v \leq^\omega w.
\]

(3) Eq. (E) gives a sufficient condition for \(v \leq^\omega w\). Is it a necessary condition?

(4) Show that \((\mathbb{N}^\omega, \leq^\omega)\) is a wqo.
(5) Generalize the previous question and show that \((A^\omega, \leq_\omega)\) is a wqo when \((A, \leq)\) is a linear wqo.

(6) We consider a finite alphabet \((\Sigma, =)\) equipped with the empty ordering. Show that its \(\omega\)-sequence extension \((\Sigma^\omega, \leq_\omega)\) is a wqo.

(7) Show that \((R^\omega, \leq_{R, \omega})\), the \(\omega\)-sequence extension of Rado’s structure \((R, \leq_R)\) — see Exercise 1.9 — is not a wqo.

Exercise 1.12 (Higman’s Lemma for Matrices?). A quasi-ordering \((A, \leq)\) leads to a natural notion of embedding on \(\text{Mat}[A]\), the set \(M, N, \ldots\) of rectangular matrices with elements from \(A\), by letting \(M \preceq_{\text{Mat}} N\) when there is a submatrix \(N'\) of \(N\) (i.e., a matrix derived from \(N\) by removing some lines and columns) s.t. \(M \preceq_{\times} N'\) (i.e., \(M\) and \(N'\) have same dimensions and \(M[i,j] \leq N'[i,j]\) for all \(i, j\)). Does \((A, \leq)\) wqo imply \((\text{Mat}[A], \leq_{\text{Mat}})\) wqo?

Exercise 1.13 (Ordering Powersets). Recall from Exercise 1.1 the definition of Smyth’s ordering on the powerset \(\mathcal{P}(A)\): if \((A, \leq)\) is a qo and \(U, V \subseteq A\) we let:

\[
U \sqsubseteq_S V \iff \forall m \in V, \exists n \in U, n \leq m .
\]

There also exists the (more natural) Hoare ordering (also called Egli-Milner ordering):

\[
U \sqsubseteq_H V \iff \forall n \in U, \exists m \in V, n \leq m .
\]

(1) What are the equivalences generated by \(\sqsubseteq_S\) and by \(\sqsubseteq_H\)?

(2) Express \(\sqsubseteq_S\) in terms of \(\sqsubseteq_H\) (and reciprocally), using set-theoretic operations like upward-closure, intersection, etc.

(3) Prove the following characterization of wqo’s:

A qo \((A, \leq)\) is wqo if, and only if, \((\mathcal{P}(A), \sqsubseteq_H)\) is well-founded. \hspace{1cm} (wqo.7)

(4) Further show that \((\mathcal{P}_f(A), \sqsubseteq_H)\) is wqo iff \((A, \leq)\) is wqo—recall that \(\mathcal{P}_f(A)\) only contains the finite subsets of \(A\).

Exercise 1.14 (Hilbert’s Basis Theorem). Given a commutative ring \((R, +, \cdot, 0, 1)\), an ideal is a subset \(I \subseteq R\) such that \(\langle I, +, 0 \rangle\) is a subgroup of \(\langle R, +, 0 \rangle\) and for all \(r\) in \(R\) and \(i\) in \(I\), \(r \cdot i\) also belongs to \(I\). An ideal \(I\) is generated by a set \(X \subseteq R\), noted \(I = I(X)\), if \(I = \{r_1 \cdot i_1 + \cdots + r_n \cdot i_n \mid n \in \mathbb{N}, r_1, \ldots, r_n \in R, i_1, \ldots, i_n \in X\}\). Of course, any ideal is generated by itself: \(I = I(I)\).

A Noetherian ring is one where every ideal is finitely generated, i.e. where for any ideal \(I\) there exist a finite set \(X = \{i_1, \ldots, i_n\} \subseteq R\) such that \(I = I(X) = \{r_1 \cdot i_1 + \cdots + r_n \cdot i_n \mid r_1, \ldots, r_n \in R\}\).

Let us fix a finite set \(\{x_1, \ldots, x_d\}\) of variables. A monomial over \(R\) is a product \(r \cdot x_{a_1}^{a_1} \cdot x_{a_2}^{a_2} \cdots x_{a_d}^{a_d}\) where the \(a_i\)’s are natural numbers; a polynomial is a finite sum of monomials. The set of polynomials \(R[x_1, \ldots, x_d]\) over \(X\) and \(R\) is again a commutative ring. Hilbert’s Basis Theorem states that, if \(R\) is Noetherian, then \(R[x_1, \ldots, x_d]\) is also Noetherian. Let us start by investigating the properties of Noetherian rings:
1. Show that any field is Noetherian.

Exercise 1.15 (Kruskal’s Tree Theorem). For a qo \( (A, \leq) \), we write \( T(A) \) for the set of finite trees node-labeled by \( A \). Formally, \( T(A) = \{ t, u, v, \ldots \} \) is the smallest set such that if \( a \in A, m \in \mathbb{N} \) and \( t_1, \ldots, t_m \in T(A) \) then the tree with root labeled by \( a \) and subtrees \( t_1, \ldots, t_m \), denoted \( a(t_1, \ldots, t_m) \), is in \( T(A) \). We order \( T(A) \) with \( \leq_T \), the homeomorphic embedding that extends \( \leq \). The definition of \( u \leq_T t \) is by induction on the structure of \( t \), with

\[
a(u_1, \ldots, u_m) \leq_T b(t_1, \ldots, t_k) \iff \begin{cases} a \leq b \\
(u_1, \ldots, u_m) \leq_{T,s} (t_1, \ldots, t_k) \\
or \exists i \in \{1, \ldots, k\} : a(u_1, \ldots, u_m) \leq_T t_i.
\end{cases}
\]

Here \( \leq_{T,s} \) denotes the sequence extension of \( \leq_T \).

1. We now assume that \( (A, \leq) \) is a wqo and prove that \( (T(A), \leq_T) \) is a wqo too. For this we assume, by way of contradiction, that \( (T(A), \leq_T) \) is not wqo. We proceed as in the proof of Higman’s Lemma (Exercise 1.10) and construct a "minimal infinite bad sequence" \( S = t_0, t_1, t_2, \ldots \) where \( t_0 \) is a smallest tree that can be used to start an infinite bad sequence, and at stage \( k, t_k \) is a smallest tree that can continue an infinite bad sequence starting with \( t_0, \ldots, t_{k-1} \). By construction \( S \) is infinite and is bad.

Let us now write every \( t_i \) in \( S \) under the form \( t_i = a_{i}(u_{i,1}, \ldots, u_{i,m_i}) \) and collect all the immediate subtrees in \( U \triangleq \{ t_{i,j} \mid i \in \mathbb{N} \land 1 \leq j \leq m_i \} \). Show that \( (U, \leq_T) \) is wqo.

2. Derive a contradiction, i.e, show that \( S \) contains an increasing pair.

At this point we conclude that our assumptions "\( A \) is wqo but \( T(A) \) is not" was contradictory, proving Kruskal’s Theorem.

Well Structured Transition Systems

Exercise 1.16 (Transitive Compatibility). We relax in this exercise \( \text{compatibility} \) to a weaker notion of compatibility, but show that \( \text{term} \) remains decidable in this setting. Consider the following replacement for \( \text{compatibility} \):

\[
s \rightarrow s' \land s \geq t \implies s' \geq t \lor \exists t' \leq s', t \rightarrow^+ t',
\]

where \( \rightarrow^+ \) is the transitive closure of \( \rightarrow \).

Show that, if \( S = (S, \rightarrow, \leq) \) is a WSTS for \( \text{(tc)} \), which is image-finite and \( \text{Post-effective} \) and has decidable \( \leq \), then one can decide whether \( S \) terminates from some state \( s_0 \) in \( S \).

Exercise 1.17 (Reflexive Transitive Compatibility). Let us relax \( \text{compatibility} \) to:

\[
s \rightarrow s' \land s \geq t \implies s' \geq t \lor \exists t' \leq s', t \rightarrow^* t',
\]

where \( \rightarrow^* \) is the reflexive transitive closure of \( \rightarrow \). We assume throughout this exercise that \( S = (S, \rightarrow, \leq) \) is a WSTS under \( \text{(rtc)} \).

1. Show that, if \( I \) is upward-closed, then \( \text{Pre}^+(I) \) is also upward-closed. Does Lemma 1.16 still hold?
(2) Let \( K_0 \) be a finite basis of \( I \). Lift \( pb \) to operate on finite sets. The sequence

\[
K_0 \subseteq K_1 \subseteq \cdots \text{ where } K_{n+1} \overset{\text{def}}{=} K_n \cup pb(K_n)
\]

converges by (wqo.4) after finitely many steps to some finite set \( K \). Show that \( \uparrow K = \uparrow \bigcup_{i \in \mathbb{N}} K_i \).

(3) Show that \( \uparrow K = \text{Pre}^* (I) \).

(4) Conclude that \( \text{Cover} \) is decidable for WSTS with (etc), effective pred-basis, and decidable \( \leq \).

Exercise 1.18 (Strict Compatibility). We strengthen in this exercise (compatibility) to a stronger notion of compatibility that allows the decidability of finiteness. Consider the following replacement for (compatibility):

\[
s \rightarrow s' \land s < t \implies \exists t', s' < t', t \rightarrow t'.
\]

Assume that \( S \) is image-finite and has strict compatibility. We further assume, for simplification purposes, that \( \leq \) is antisymmetric (i.e., it is a partial order, where different elements cannot be equivalent). A run \( s_0 \rightarrow s_1 \rightarrow s_2 \rightarrow \cdots \) is repeats-free if \( s_i \neq s_j \) whenever \( i \neq j \).

(1) Show that \( S \) has an infinite repeats-free run starting from \( s_0 \) iff \( \text{Post}^* (s_0) \) is infinite.

(2) Show that \( S \) has an infinite repeats-free run from \( s_0 \) iff it has a finite repeats-free run that contains an increasing pair, i.e., some \( i < j \) with \( s_i \leq s_j \).

(3) Conclude that the following problem is decidable for image-finite, Post-effective WSTSs with strict compatibility and decidable and antisymmetric \( \leq \):

[Fin] Finiteness

\[
\text{instance: } \text{A transition system } \langle S, \rightarrow \rangle, \text{ a qo } (S, \leq), \text{ and a state } s_0 \in S.
\]

\[
\text{question: Is } \text{Post}^* (s_0) \text{ finite?}
\]

(4) Generalize the previous result so that one does not require antisymmetry of \( \leq \).

Exercise 1.19 (Downward WSTSs). Let \( \langle S, \rightarrow \rangle \) be a transition system and \( (S, \leq) \) be a wqo. The definition of (compatibility) is also known as "upward-compatibility", by contrast with its dual reflexive downward compatibility:
20 Chapter 1. Basics of WQOs and Applications

\[ s \rightarrow s' \land s \geq t \text{ implies } s' \geq t \lor \exists t' \leq s', \ t \rightarrow t'. \]  

(rdC) 

that defines a downward WSTS \( S = (S, \rightarrow, \leq) \).

Show that the following problem is decidable for image-finite, Post-effective downward WSTSs with decidable \( \leq \):

**[SCover]** Sub-Coverability

**instance:** A transition system \( (S, \rightarrow) \), a qo \( (S, \leq) \), and two states \( s, t \) in \( S \).

**question:** Is there a run \( s = s_0 \rightarrow s_1 \rightarrow \cdots \rightarrow s_n \leq t \)?

**Exercise 1.20** (WSTSs Everywhere). We consider a transition system \( S = (S, \rightarrow) \) where \( S \) is a recursive (but otherwise arbitrary) set of configurations. For \( s \in S \), let \( \text{maxtime}(s) \) be the length of the longest run starting from \( s \). We let \( \text{maxtime}(s) = \omega \) when arbitrary long runs exist. Define \( s \leq_T t \) when \( \text{maxtime}(s) \leq \text{maxtime}(t) \) assuming the obvious total ordering over \( \mathbb{N} \cup \{\omega\} \).

(1) Show that \( (S, \rightarrow, \leq_T) \) is a WSTS.

(2) Can we use WSTS theory and decide whether \( S \) terminates (starting from some \( s_0 \)) when it is Post-effective and image-finite?

**Program Termination**

**Exercise 1.21.** Show that the weaker condition

\[ R \subseteq T_1 \cup \cdots \cup T_k \]  

with each \( T_j \) is well-founded does not imply \( R \) well-founded.

**Exercise 1.22** (Disjunctive Termination Arguments). Assume that a binary relation \( R \) verifies \( (1.10) \) on page \( 8 \), where each \( T_j \) is well-founded. Prove using the Infinite Ramsey Theorem that \( R \) is well-founded.

**Relevance Logic**

**Exercise 1.23** (Cut Elimination & Subformula Property). Prove \( \text{Lemma 1.18} \).

**Exercise 1.24** (A WSTS for Relevant Implication). Prove that \( S \) defined by equations \( (1.18) \) and \( (1.19) \) is a WSTS with effective pred-basis and decidable ordering.

**Exercise 1.25** (Proof Search for Relevant Implication). The purpose of this exercise is to find an alternative algorithm for \( R \). The key idea in this algorithm is to remove \( \text{(Con)} \) from \( R' \) and apply contractions only when needed, i.e. modify the rules \( \text{(L)} \) and \( \text{(R)} \) to contract their conclusion, but only inassomuch as could not be obtained by first contracting their premises. Doing so we define an alternative proof system \( R_0 \) that includes the unmodified \( \text{(Ax)} \) and \( \text{(C)} \), and a modified version of \( \text{(L)} \):

\[ \frac{\alpha \vdash A \quad \beta B \vdash C}{\gamma \vdash C} \quad (\Rightarrow_0') \]
where $\gamma \vdash C \ll \alpha\beta(A \supset B) \vdash C$ is such that, for all formulae $D$, $\gamma(D) \geq \alpha(D) + \beta(D) - 1$.

(1) Show how any derivation of a sequent $\alpha \vdash B$ in $R \cup R'$ can be transformed into a derivation in $R'$ of no larger height.

(2) Deduce that $R'$ and $R$ derive the same sequents.

(3) Deduce that, if $\alpha \vdash B \ll \alpha' \vdash B'$ and $\alpha' \vdash B'$ has a derivation of height $n$ in $R'$, then $\alpha \vdash B$ has a derivation of height at most $n$ in $R'$.

(4) We work now in the modified calculus $R'$. We say that a derivation in $R'$ is irredundant if, by following any branch starting from the root to the leaves, we never first meet $\alpha \vdash B$ and later $\alpha' \vdash B'$ with $\alpha \vdash B \ll \alpha' \vdash B'$. Show that $R'$ is decidable by proof search using König’s Lemma and Kripke’s Lemma.

**Karp & Miller Trees**

Exercise 1.26. Show that $\mathbb{N}_\omega$ is a wqo.

Exercise 1.27 (Covering). The aim of this exercise is to complete the proof of Theorem 1.21 and show that the set of labels $C \subseteq \mathbb{N}_\omega$ of the Karp & Miller tree $T$ forms a covering according to Definition 1.20.

(1) Let $\text{neg}(a)$ be the vector in $\mathbb{N}^d$ defined by

$$\text{neg}(a)(j) = \begin{cases} -a(j) & \text{if } a(j) \leq 0 \\ 0 & \text{otherwise} \end{cases}$$

for $a$ in $\mathbb{Z}^d$ and $j$ in $\{1, \ldots, d\}$. The threshold $\Theta(u)$ of a transition sequence $u$ in $A^*$ is the minimal configuration $x$ in $\mathbb{N}^d$ s.t. $u$ is enabled from $x$, i.e. there exists $x'$ s.t. $x \xrightarrow{u} x'$. Show how to compute $\Theta(u)$. Show that $\Theta(uv) \leq \Theta(u) + \Theta(v)$ for all $u, v$ in $A^*$.

(2) In order to prove that $C$ satisfies Definition 1.20, we will prove a stronger statement. For an $\omega$-marking $y$ in $\mathbb{N}^d_\omega$, first define

$$\Omega(y) \overset{\text{def}}{=} \{ j = 1, \ldots, d \mid y(j) = \omega \}$$

the set of $\omega$-components of $y$, and

$$\overline{\Omega}(y) \overset{\text{def}}{=} \{ 1, \ldots, d \} \setminus \Omega(y)$$

its set of finite components. We introduce for this question a variant of the construction found in the main text, which results in a Karp & Miller graph $G$ instead of a tree: in step [4] we rather add an edge $s \xrightarrow{a} s_i$. Observe that this does not change $C$ nor the termination of the algorithm.

Show that, if $x_0 \xrightarrow{u} x$ for some translation sequence $u$ in $A^*$, then there exists a node $s$ in $G$ labeled by $y$ such that $x(j) = y(j)$ for all $j$ in $\overline{\Omega}(y)$ and $s_0 \xrightarrow{u} s$ is a path in the graph.
(3) Let us prove that $C$ satisfies Definition 1.20. The idea is that we can find reachable configurations of $V$ that agree with $y$ on its finite components, and that can be made arbitrarily high on its $\omega$-components. For this, we focus on the graph nodes where new $\omega$ values are introduced by step 2, which we call $\omega$-nodes.

Prove that, if $s_0 \xrightarrow{u} s$ labeled $y$ for some $u$ in $A^*$ in the tree and $z$ in $\mathbb{N}^{\Omega(y)}$ is a partial configuration on the components of $\Omega(y)$, then there are

- $n$ in $\mathbb{N}$,
- a decomposition $u = u_1u_2\cdots u_{n+1}$ with each $u_i$ in $A^*$ where the nodes $s_i$ reached by $s_0 \xrightarrow{u_1\cdots u_i} s_i$ for $i \leq n$ are $\omega$-nodes,
- sequences $w_1, \ldots, w_n$ in $A^+$,
- numbers $k_1, \ldots, k_n$ in $\mathbb{N}$,

such that $x_0 \xrightarrow{u_1w_1^{k_1}u_2\cdots u_nw_n^{k_n}u_{n+1}} y \xrightarrow{v} x$ with $x(j) = y(j)$ for all $j$ in $\Omega(y)$ and $x(j) \geq z(j)$ for all $j$ in $\Omega(y)$. Conclude.

Bibliographic Notes

**Well Quasi Orders** are "a frequently discovered concept", to quote the title of a survey by Kruskal (1972). Nevertheless, much of the theory appears in Higman (1952), although Dickson’s Lemma already appeared (in a rather different form) in (Dickson, 1913). The reader will find more information in the survey of Milner (1985), which also covers *better quasi orders* (bqo), which allow to handle the problematic constructions of exercises 1.11 to 1.13—see Marcone (1994) for a good reference, and Rado (1954) or Jančar (1999) for a characterization of the wqos for which $\mathcal{P}(A), \subseteq_S$ and/or $A^\omega, \leq_\omega$ is also a wqo. See Lovász (2006) for an exposition of Robertson and Seymour’s Graph-Minor Theorem, its underlying ideas, and its consequences in graph theory.

**Well Structured Transition Systems** have been developed in different directions by Finkel (1987, 1990) and Abdulla et al. (1996), before a unifying theory finally emerged in the works of Abdulla et al. (2000) and Finkel and Schnoebelen (2001)—the latter being our main source for this chapter and exercises 1.16 to 1.19. More recent developments are concerned with the algorithmics of downward-closed sets (Finkel and Goubault-Larrecq, 2009, 2012) and of games (Abdulla et al., 2008; Bertrand and Schnoebelen, 2013).

**Program Termination.** Proving termination thanks to a ranking function into a well-founded ordering can be traced back at least to Turing (1949). The presentation in these notes rather follows Cook et al. (2011) and emphasizes the interest of transition invariants; see Podolski and Rybalchenko (2004) and the discussion of related work by Blass and Gurevich (2008).

**Relevance Logic.** The reader will find a good general exposition on relevance logic in the chapter of Dunn and Restall (2002), and in particular a discussion of decidability issues in their Section 4, from which Exercise 1.25 is taken (credited to Kripke, 1959). Both the approach in the exercise and that of the main text scale to larger fragments like the conjunctive implicative fragment $\mathbf{R}_{\wedge, \wedge}$, but Urquhart (1984) proved the undecidability of the
full relevance logic $\mathcal{R}$ and its variants the entailment logic $\mathcal{E}$ and ticket logic $\mathcal{T}$. This is still an active area of research: although Urquhart (1999) proved $\mathcal{R}_{\land, \lor}$ to be Ackermannian (see CR on page 91), the complexity of $\mathcal{R}$ is still unknown; similarly the decidability of implicative ticket logic $\mathcal{T}_{\supset}$ was only recently proven by Padovani (2012), and its complexity is also unknown.

Karp & Miller Trees and vector addition systems were first defined by Karp and Miller (1969). Coverability trees are used in a large number of algorithms and decision procedures on VAS, although their worst-case size can be Ackermannian in the size of the input VAS (Cardoza et al., 1976). Quite a few of these problems, including termination and coverability, can actually be solved in $\text{EXPSPACE}$ instead (Rackoff, 1978; Blockelet and Schmitz, 2011), but finite equivalences are an exception (Mayr and Meyer, 1981; Jančar, 2001); see FCP on page 90. The notion of covering can be generalized to complete WSTS, but they are in general not finite as in the VAS case (Finkel and Goubault-Larrecq, 2012).
As seen in Chapter 1, many algorithms rely on well quasi orderings to prove the termination. Although it is true that the classical proofs of Dickson’s Lemma, Higman’s Lemma, and other wqos, are infinitistic in nature, the way they are typically applied in algorithms lends itself to constructive proofs, from which complexity upper bounds can be extracted and applied to evaluate algorithmic complexities.

We present in this chapter how one can derive complexity upper bounds for these algorithms as a side-product of the use of Dickson’s Lemma over tuples of integers. The techniques are however quite generic and also apply to more complex wqos; see the Bibliographic Notes at the end of the chapter.

**BAD SEQUENCES AND TERMINATION.** Recall from Definition 1.1 that one of the characterizations for \((A, \leq)\) to be a wqo is that every infinite sequence \(a_0, a_1, \ldots\) over \(A\) contains an increasing pair \(a_{i_1} \leq a_{i_2}\) for some \(i_1 < i_2\). We say that (finite or infinite) sequences with an increasing pair \(a_{i_1} \leq a_{i_2}\) are good sequences, and call bad a sequence where no such increasing pair can be found. Therefore every infinite sequence over the wqo \(A\) is good, i.e., bad sequences over \(A\) are finite.

```
SIMPLE (a, b)
c ← 1
while a > 0 ∧ b > 0
    l := ⟨a, b, c⟩ ← ⟨a − 1, b, 2c⟩
or
    r := ⟨a, b, c⟩ ← ⟨2c, b − 1, 1⟩
end
```

Figure 2.1: SIMPLE: A simple while program, repeated from Figure 1.1.

Recall the SIMPLE program from Figure 1.1 on page 7, repeated here in Figure 2.1. We argued on page 7 that, in any run, the sequence of values taken by a
and b
\begin{equation}
\langle a_0, b_0 \rangle, \ldots, \langle a_j, b_j \rangle, \ldots,
\end{equation}
is a bad sequence over \((\mathbb{N}^2, \leq)\), and by \textbf{Dickson’s Lemma}, it is finite, which means that \textsc{simple} always terminates.

In this chapter, we are going to see that the very fact that we applied \textbf{Dickson’s Lemma} yields more that just the termination of \textsc{simple}: it also yields an upper bound on the number of times its main loop can be unrolled as a function of its initial input \(\langle a_0, b_0 \rangle\), i.e. a bound on the length of the bad sequence \((2.1)\). Better, the upper bounds we will prove are highly \textit{generic}, in that we only need to find out the complexity of the operations (i.e. only linear operations in \textsc{simple}) and the dimension we are working with (i.e. in dimension 2 in \((2.1)\)), to provide an upper bound.

\textbf{A LOWER BOUND.} Before we investigate these upper bounds, let us have a look at how long \textsc{simple} can run: for instance, for \(\langle a_0, b_0 \rangle = \langle 2, 3 \rangle\), we find the following run
\[\langle 2, 3, 2^0 \rangle \xrightarrow{L} \langle 1, 3, 2^1 \rangle \xrightarrow{L} \langle 2^2, 2, 2^0 \rangle \xrightarrow{L^{2^2-1}R} \langle 2^{2^2}, 1, 1 \rangle \xrightarrow{L^{2^{2^2}-1}R} \langle 0, 1, 2^{2^{2^2}} \rangle,\]
of length
\[2 + 2^2 + 2^{2^2},\]
which is non-elementary in the size of the initial values. This is instructive: linear operations and dimension 2 constitute the simplest case we care about, and the complexities we find are already beyond the elementary hierarchies, where the distinctions time vs. space resources, or deterministic vs. nondeterministic computations, become irrelevant. Hierarchies for non-elementary complexities are maybe not so well-known, so we will introduce one such hierarchy, the \textit{Grzegorczyk hierarchy} \((\mathcal{F}_k)_{k \in \mathbb{N}}\) of classes of functions (see Figure 2.2).

As we will see, in the case of \textsc{simple}, we can show there exists a function bounding the length of all runs and residing in \(\mathcal{F}_3\), which is the lowest level to

![Figure 2.2: The Grzegorczyk hierarchy of primitive-recursive functions.](image-url)
contain non-elementary functions. Chapter 3 will be devoted to further matching complexity lower bounds for decision problems on monotonic counter systems.

OUTLINE. The upcoming Section 2.1 surveys all the notions (controlled sequences, polynomial normed wqos, and the Grzegorczyk hierarchy) needed in order to state the Length Function Theorem, and later apply it to several algorithms in Section 2.2. The proof of the theorem is delayed until Section 2.3, which ends with the definition of a bounding function $M$ on the length of controlled bad sequences, and Section 2.4 that classifies this function inside the Grzegorczyk hierarchy.

## 2.1 The Length of Controlled Bad Sequences

As seen with the example of Simple, wqo-based termination arguments rely on the finiteness of bad sequences. In order to further provide a complexity analysis, our goal is thus to bound the length of bad sequences.

### 2.1.1 Controlled Sequences

Our first issue with our program is that one can construct arbitrarily long bad sequences, even when starting from a fixed first element. Consider $\mathbb{N}^2$ and fix $x_0 = (0, 1)$. Then the following

\[
(0, 1), (L, 0), (L - 1, 0), (L - 2, 0), \ldots, (2, 0), (1, 0)
\]

is a bad sequence of length $L + 1$. What makes such examples possible is the “uncontrolled” jump from an element like $x_0$ to an arbitrarily large next element, here $x_1 = (L, 0)$. Indeed, when one only considers bad sequences displaying some controlled behaviour (in essence, bad sequences of bounded complexity, as with the linear operations of Simple), upper bounds on their lengths certainly exist.

**Norms and Controls.** In order to control the growth of the values in a sequence $a_0, a_1, a_2, \ldots$ over some wqo $(A, \leq)$, we introduce two main ingredients:

1. the first is a norm $|.|_A: A \to \mathbb{N}$ on the elements to represent their size. We always assume $A_{\leq n} \defeq \{ a \in A \mid |a|_A \leq n \}$ to be finite for every $n$; we call the resulting structure $(A, \leq, |.|_A)$ a normed wqo (nwqo). For instance, for $\mathbb{N}^2$ we will use the infinite norm $\langle m, n \rangle_{\mathbb{N}^2} \defeq \max(m, n)$;

2. the second is a control function $g: \mathbb{N} \to \mathbb{N}$ used to bound the growth of elements as we iterate through the sequence. We always assume $g$ to be strictly increasing: $g(x + 1) \geq 1 + g(x)$ for all $x$. 

Mixing these together, we say that a sequence \( a_0, a_1, a_2, \ldots \) over \( A \) is \((g, n)\)-controlled for some initial norm \( n \in \mathbb{N} \) if

\[
\forall i = 0, 1, 2, \ldots : |a_i|_A \leq g^i(n) \overset{\text{def}}{=} \underbrace{g(g(\cdots g(n)))}_{\text{i times}}.
\]  

(2.4)

In particular, \( |a_0|_A \leq n \), hence the name “initial norm” for \( n \). For instance, the bad sequence \((2.1)\) over \( \mathbb{N}^2 \) extracted from the runs of simple is \((g, n)\)-controlled for \( g(x) = 2x \) and \( n = \max(a_0, b_0) \). Observe that the empty sequence is always a controlled sequence.

**Definition 2.1 (Basic nwqos).** We note \([k]\) the nwqo \(\{0, \ldots, k-1\} \subset [.|[k]]\) defined over the initial segment of the natural numbers, where \(|j|_{[k]} \overset{\text{def}}{=} j\) for all \(0 \leq j < k\), and \(\Gamma_k\) the generic \(k\)-elements nwqo \(\{a_0, \ldots, a_{k-1}\} \subset [.|\Gamma_k]\) where \(|a_j|_{\Gamma_k} \overset{\text{def}}{=} 0\) for all \(0 \leq j < k\).

**Length Function.** The outcome of these definitions is that, unlike in the uncontrolled case, there is a longest \((g, n)\)-controlled bad sequence over any nwqo \((A, \leq_A, |.|_A)\): indeed, we can organize such sequences in a tree by sharing common prefixes; this tree has

- finite branching degree, bounded by the cardinal of \(A_{\leq g^i(n)}\) for a node at depth \(i\), and
- finite depth thanks to the wqo property.

By König’s Lemma, this tree of bad sequences is therefore finite, of some height \(L_{g,A}(n)\) representing the length of the maximal \((g, n)\)-controlled bad sequence(s) over \(A\). In the following, since we are mostly interested in this length as a function of the initial norm, we will see this as a length function \(L_{g,A}(n)\); our purpose will then be to obtain complexity bounds on \(L_{g,A}(n)\).

**Remark 2.2 (Monotonicity of \(L\)).** It is easy to see that \(L_{g,A}(n)\) is monotone in the initial norm \(n\) (because \(g\) is increasing), but also in the choice of the control function: if \(h(x) \geq g(x)\) for all \(x\), then a \((g, n)\)-controlled bad sequence is also an \((h, n)\)-controlled one, thus \(L_{g,A}(n) \leq L_{h,A}(n)\).

### 2.1.2 Polynomial nwqos

Before we go any further in our investigation of the length function, let us first restrict the scope of our analysis.

**Isomorphisms.** For one thing, we will work up to isomorphism: we write \(A \equiv B\) when the two nwqo’s \(A\) and \(B\) are isomorphic structures. For all practical purposes, isomorphic nwqos can be identified. Let us stress that, in particular, norm functions must be preserved by nwqo isomorphisms. Obviously, the length functions \(L_{g,A}\) and \(L_{g,B}\) are the same for isomorphic nwqos.
Example 2.3 (Isomorphisms). On the positive side, $[0] \equiv \Gamma_0$ and also $[1] \equiv \Gamma_1$ since $|a_0|_{\Gamma_1} = 0 = |0|_{[1]}$.

However, $[2] \not\equiv \Gamma_2$: not only these two have non-isomorphic orderings, but they also have different norm functions. This can be witnessed by their associated length functions: one can see for instance that “$a_1, a_0$” is a $(g, 0)$-controlled bad sequence over $\Gamma_2$, but that the longest $(g, 0)$-controlled bad sequence over $[2]$ is the sequence “0” of length 1.

**Polynomial nwqos.** We are now ready to define the class of normed nwqos we are interested in. We will need the empty nwqo $\Gamma_0 = \emptyset$, and a singleton nwqo $\Gamma_1$ containing a single element with norm 0, and using equality as ordering as in Example 2.3. The exact element found in this singleton is usually irrelevant; it could be for instance a letter in an alphabet, or a state in a finite state set.

The **disjoint sum** of two nwqos $(A_1, \leq_{A_1}, |.|_{A_1})$ and $(A_2, \leq_{A_2}, |.|_{A_2})$ is the nwqo $(A_1 + A_2, \leq_{A_1 + A_2}, |.|_{A_1 + A_2})$ defined by

$$A_1 + A_2 \overset{\text{def}}{=} \{ \langle i, a \rangle \mid i \in \{1, 2\} \text{ and } a \in A_i \} \,,$$

$$\langle i, a \rangle \leq_{A_1 + A_2} \langle j, b \rangle \overset{\text{def}}{\iff} i = j \text{ and } a \leq A_i b \,,$$

$$|\langle i, a \rangle|_{A_1 + A_2} \overset{\text{def}}{=} |a|_{A_i} \,.$$  

We write $A \cdot k$ for $A + \cdots + A$; then, any finite nwqo $\Gamma_k$ can be defined as a $k$-ary disjoint sum $\Gamma_k \overset{\text{def}}{=} \Gamma_1 \cdot k$.

The **cartesian product** of two nwqos $(A_1, \leq_{A_1}, |.|_{A_1})$ and $(A_2, \leq_{A_2}, |.|_{A_2})$ is the nwqo $(A_1 \times A_2, \leq_{A_1 \times A_2}, |.|_{A_1 \times A_2})$ defined by

$$A_1 \times A_2 \overset{\text{def}}{=} \{ \langle a_1, a_2 \rangle \mid a_1 \in A_1, a_2 \in A_2 \} \,,$$

$$\langle a_1, a_2 \rangle \leq_{A_1 \times A_2} \langle b_1, b_2 \rangle \overset{\text{def}}{\iff} a_1 \leq A_1 b_1 \text{ and } a_2 \leq A_2 b_2 \,,$$

$$|\langle a_1, a_2 \rangle|_{A_1 \times A_2} \overset{\text{def}}{=} \max_{i \in \{1, 2\}} |a_i|_{A_i} \,.$$  

The fact that $A_1 \times A_2$ is indeed a wqo is known as Dickson’s Lemma. We note the $d$-fold cartesian product of a nwqo $A$ with itself $A^d \overset{\text{def}}{=} A \times \cdots \times A$; in particular $A^0 \equiv \Gamma_1$ is a singleton set containing only the empty tuple, of size 0 by (2.10).

Last, as we will be working on natural numbers, we also need the **naturals nwqo** $\mathbb{N}$ along with its usual ordering and the norm $|k|_{\mathbb{N}} \overset{\text{def}}{=} k$ for all $k$ in $\mathbb{N}$.

**Definition 2.4.** The set of **polynomial nwqos** is the smallest set of nwqos containing $\Gamma_0, \Gamma_1$, and $\mathbb{N}$ and closed under the + and × operations.

Example 2.5 (VASS Configurations). One can see that the set of configurations $Conf$ of a $d$-dimensional VASS over a set of states $Q$ with $|Q| = p$, along with its ordering, is isomorphic to the polynomial nwqo $\mathbb{N}^d \times \Gamma_p$.

Remark 2.6 (nwqo Semiring). Observe that the definitions are such that all the expected identities of + and × hold: the class of all nwqos when considered up
to isomorphism forms a \textit{commutative semiring}: $\Gamma_0$ is neutral for $+$ and absorbing for $\times$:

$$\Gamma_0 + A \equiv A + \Gamma_0 \equiv A \quad \Gamma_0 \times A \equiv A \times \Gamma_0 \equiv \Gamma_0 \, , \tag{2.11}$$

$\Gamma_1$ is neutral for $\times$:

$$\Gamma_1 \times A \equiv A \times \Gamma_1 \equiv A \, , \tag{2.12}$$

$+$ is associative and commutative:

$$A + (B + C) \equiv (A + B) + C \quad A + B \equiv B + A \, , \tag{2.13}$$

$\times$ is associative and commutative:

$$A \times (B \times C) \equiv (A \times B) \times C \quad A \times B \equiv B \times A \, , \tag{2.14}$$

and $\times$ distributes over $+$:

$$(A + B) \times C \equiv (A \times C) + (B \times C) \, . \tag{2.15}$$

\textbf{Remark 2.7 (Normal Form for Polynomial nwqos).} An easy consequence of the identities from Remark 2.6 for polynomial nwqos is that any polynomial nwqo $A$ can be put in a \textit{polynomial normal form} (PNF)

$$A \equiv \mathbb{N}^{d_1} + \cdots + \mathbb{N}^{d_m} \tag{2.16}$$

for $m, d_1, \cdots, d_m \geq 0$. In particular, we denote the PNF of $\Gamma_0$ by “0.” In Section 2.3.3 and later sections we will deal exclusively with nwqos in PNF; since $A \equiv A'$ implies $L_{g,A} = L_{g,A'}$ this will be at no loss of generality.

\subsection{Subrecursive Functions}

We already witnessed with simple that the complexity of some programs implementable as monotone counter systems can be quite high—more than a tower of exponentials $2^{2^{\cdots^{2^b}}}$ \textit{b times} for \texttt{simple}(2, b) in Equation (2.2) on page 26, which is a non-elementary function of $b$. However there is a vast space of functions that are non-elementary but recursive—and even primitive recursive, which will be enough for our considerations.

\textbf{The Grzegorczyk Hierarchy} $(\mathcal{F}_k)_{k<\omega}$ is a hierarchy of classes of primitive-recursive functions $f$ with argument(s) and images in $\mathbb{N}$. Their union is exactly the set of primitive-recursive functions:

$$\bigcup_{k<\omega} \mathcal{F}_k = \text{FPR} \, . \tag{2.17}$$

The lower levels correspond to reasonable classes, $\mathcal{F}_0 = \mathcal{F}_1$ being the class of linear functions, and $\mathcal{F}_2$ that of elementary functions. Starting at level 1, the hierarchy is strict in that $\mathcal{F}_k \subset \mathcal{F}_{k+1}$ for $k > 0$ (see Figure 2.2 on page 26).

At the heart of each $\mathcal{F}_k$ lies the $k$th \textit{fast-growing function} $F_k : \mathbb{N} \to \mathbb{N}$, which
is defined for finite $k$ by
\[ F_0(x) \overset{\text{def}}{=} x + 1, \quad F_{k+1}(x) \overset{\text{def}}{=} F_k^{x+1}(x) = \overbrace{F_k(F_k(\cdots F_k(x)))}^{x+1 \text{ times}}. \tag{2.18} \]
This hierarchy of functions continues with ordinal indices, e.g.
\[ F_\omega(x) \overset{\text{def}}{=} F_\omega(x). \tag{2.19} \]
Observe that
\[ F_1(x) = 2x + 1, \quad F_2(x) = 2^{x+1}(x + 1) - 1, \tag{2.20} \]
\[ F_3(x) > 2^{2^{\cdots^{2}}} \text{ } x \text{ times} \text{ etc.} \tag{2.21} \]
For $k \geq 2$, each level of the Grzegorczyk hierarchy can be characterized as
\[ \mathcal{R}_k = \{ f \mid \exists i, \ f \text{ is computed in time/space } \leq F_k^i \}, \tag{2.22} \]
the choice between deterministic and nondeterministic or between time-bounded and space-bounded computations being irrelevant because $F_2$ is already a function of exponential growth.

On the one hand, because the fast-growing functions $F_k$ are honest, i.e. can be computed in time bounded by a function elementary in $F_k$, $F_k \in \mathcal{R}_k$ for all $k$. On the other hand, every function $f$ in $\mathcal{R}_k$ is eventually bounded by $F_{k+1}$, i.e. there exists a rank $x_f$ s.t. for all $x_1, \ldots, x_n$, if $\max_i x_i \geq x_f$, then $f(x_1, \ldots, x_n) \leq F_{k+1}(\max_i x_i)$. However, for all $k > 0$,
\[ F_{k+1} \not\in \mathcal{R}_k. \tag{2.23} \]
In particular, $F_\omega$ is (akin to) the diagonal Ackermann function: it is not primitive-recursive and eventually bounds every primitive recursive function.

We delay more formal details on $(\mathcal{R}_k)_k$ until Section 2.4 on page 40 and Exercise 2.3 on page 48 and turn instead to the main theorem of the chapter.

### 2.1.4 Upper Bounds for Dickson’s Lemma

#### Theorem 2.8 (Length Function Theorem). Let $g$ be a control function bounded by some function in $\mathcal{F}_\gamma$ for some $\gamma \geq 1$ and $d, p \geq 0$. Then $L_{g, \mathbb{N}^d, \Gamma_p}$ is bounded by a function in $\mathcal{F}_{\gamma+d}$.

The Length Function Theorem is especially tailored to give upper bounds for VASS configurations (recall Example 2.5 on page 29), but can also be used for VASS extensions. For instance, the runs of simple can be described by bad sequences in $\mathbb{N}^2$, of form described by Equation (2.1) on page 26. As these sequences are controlled by the linear function $g(x) = 2x$ in $\mathcal{F}_1$, the Length Function Theorem with $p = \gamma = 1$ entails the existence of a bounding function in $\mathcal{F}_3$ on the length of any run of simple, which matches the non-elementary length of the example run we provided in (2.2).
2.2 Applications

Besides providing complexity upper bounds for various problems, the results presented in this chapter also yield new “combinatorial” algorithms: we can now employ an algorithm that looks for a witness of bounded size. We apply this technique in this section to the two WSTS algorithms presented in Section 1.2.

Exercise 2.4 investigates the application of the Length Function Theorem to the program termination proofs of Section 1.3.1 and Exercise 2.14 to the Karp & Miller trees of Section 1.3.3. These applications remain quite generic, thus to make matters more concrete beforehand, let us mention that, in the case of vector addition systems with states (Example 1.13), lossy counter machines (Section 3.1), reset machines (Section 3.5), or other examples of well-structured counter machines with transitions controlled by \( g(x) = x + b \) for some \( b \)—which is a function in \( R \), with \( d \) counters, and with \( p \) states, the Length Function Theorem yields an upper bound in \( F_{d+1} \) on the length of controlled bad sequences. This is improved to \( F_d \) by Corollary 2.36 on page 46. When \( b \) or \( p \) is part of the input, this rises to \( F_{d+1} \), and when \( d \) is part of the input, to \( F_d \), which asymptotically dominates every primitive-recursive function.

2.2.1 Termination Algorithm

Let us consider the Termination problem of Section 1.2.1. Let \( S = \langle S, \rightarrow, \leq \rangle \) be a WSTS over a normed wqo \((S, \leq, |.|)\) where the norm \(|.|\) is also the size for a concrete representation of elements in \( S \), let \( s_0 \) be an initial state in \( S \) with \( n = |s_0| + 1 \), and let \( g(|s|) \) be an upper bound on the space required to compute some \( s' \) from \( s \) verifying \( s \rightarrow s' \). We can reasonably expect \( g \) to be increasing and honest, and use it as a control over sequences of states: we compute an upper bound

\[
f(n) \geq L_{g,S}(n).
\]  

(2.24)

As the Length Function Theorem and all the related results allow to derive honest upper bounds, this value can be computed in space elementary-recursive in \( f \).

Because any run of \( S \) of length \( \ell \triangleq f(n) + 1 \) is necessarily good, we can replace the algorithm in the proof of Proposition 1.15 by an algorithm that looks for a finite witness of non-termination of form

\[
s_0 \rightarrow s_1 \rightarrow \cdots \rightarrow s_\ell.
\]  

(2.25)

This algorithm requires space at most \( g^\ell(n) \) at any point \( i \) to compute some \( s_{i+1} \), which yields a nondeterministic algorithm working in space elementary in \( g^\ell(n) \). This falls in the same class as \( f(n) \) itself in our setting—see Exercise 2.13 for an analysis of \( g^\ell \).
2.2.2 Coverability Algorithm

Recall that the algorithm of Section 1.2.2 for WSTS coverability of \( t \) from \( s \), relied on the saturation of a sequence (1.4) on page 6 of subsets of \( S \). In order to derive an upper complexity bound on this problem, we look instead at how long we might have to wait until this sequence proves coverability, i.e. consider the length of

\[
\uparrow\{t\} = I_0 \subseteq I_1 \subseteq \cdots \subseteq I_\ell, \text{ where } s \in I_\ell \text{ but } s \notin I_i \text{ for any } i < \ell. \tag{2.26}
\]

For each \( i = 1, \ldots, \ell \), let \( s_i \) be a minimal element in the non-empty set \( I_i \setminus I_{i-1} \); then there must be one such \( s_\ell \leq s \) that does not appear in any of the \( I_i \) for \( i < \ell \), and we consider a particular sequence

\[
s_1, s_2, \ldots, s_\ell \leq s \tag{2.27}
\]

Note that \( s_j \nless s_i \) for \( j > i \), since \( s_j \notin I_i \) and the sequence \( s_1, s_2, \ldots \) in (2.27) is bad—this also proves the termination of the \( (I_i)_i \) sequence in (2.26).

We now need to know how the sequence in (2.27) is controlled. Note that in general \( s_i \not\rightarrow s_{i+1} \), thus we really need to consider the sets of minimal elements in (2.26) and bound more generally the length of any sequence of \( s_i \)'s where each \( s_i \) is a minimal element of \( I_i \setminus I_{i-1} \). Assume again that \( \mathcal{S} = (S, \rightarrow, \leq) \) is a WSTS over a normed wqo \( (S, \leq, |.|) \) where the norm \(|.|\) is also the size for a concrete representation of states in \( S \). Also assume that \( s' \leq s \) can be tested in space elementary in \(|s'| + |s|\), and that elements of \( \text{pb}(s) \) can be computed in space \( g(|s|) \) for a honest increasing \( g \): then \( \ell \leq L_{g,\mathcal{S}}(|t| + 1) \).

There is therefore a sequence

\[
t = s_0, s_1', \ldots, s_\ell' = s_\ell \leq s \text{ where } s_{i+1}' \in \text{pb}(s_i') \tag{2.28}
\]

of minimal elements in \( (I_i)_i \) that eventually yields \( s_\ell \leq s \). We derive again a nondeterministic algorithm that looks for a witness (2.28) of bounded length. Furthermore, each \( s_i' \) verifies \(|s_i'| \leq g^\ell(|t| + 1)\), which means that this algorithm works in nondeterministic space elementary in \( g^\ell(|t| + 1) + |s| \).

2.3 Bounding the Length Function

This section and the next together provide a proof for the Length Function Theorem. The first part of this proof investigates the properties of bad controlled sequences and derives by induction over polynomial nwqos a bounding function \( M_{g, A}(n) \) on the length of \((g, n)\)-controlled bad sequences over \( A \) (see Proposition 2.20 on page 40). The second part, detailed in Section 2.4, studies the properties of the \( M_{g, A} \) functions, culminating with their classification in the Grzegorczyk hierarchy.
2.3.1 Residual nwqos and a Descent Equation

Returning to the length function, let us consider a very simple case, namely the case of sequences over \( \mathbb{N} \): one can easily see that

\[
L_{g, \mathbb{N}}(n) = n
\]  

(2.29)

because the longest \((g, n)\)-controlled bad sequence over \( \mathbb{N} \) is simply \( n, n - 1, \ldots, 1, 0 \)

(2.30)

of length \( n + 1 \).

Formally, (2.30) only proves one direction of (2.29), which is that \( L_{g, \mathbb{N}}(n) \geq n \); an argument for the converse inequality could use roughly the following lines: in any \((g, n)\)-controlled bad sequence of natural integers \( k, l, m, \ldots \) over \( \mathbb{N} \), once the first element \( k \leq n \) has been fixed, the remaining elements \( l, m, \ldots \) have to be chosen inside a finite set \( \{0, \ldots, k - 1\} \) of cardinal \( k \)—or the sequence would be good. Thus this suffix, which itself has to be bad, is of length at most

\[
L_{g, \Gamma_k}(n) = k
\]

(2.31)

by the pigeonhole principle. Choosing \( k = n \) maximizes the length of the bad sequence in (2.31), which shows that \( L_{g, \mathbb{N}}(n) \leq n + 1 \).

This argument is still a bit blurry (and will soon be cleared out), but it already contains an important insight: in a \((g, n)\)-controlled bad sequence \( a_0, a_1, a_2, \ldots \) over some nwqo \( A \), we can distinguish between the first element \( a_0 \), which verifies \( |a_0|_A \leq n \), and the suffix sequence \( a_1, a_2, \ldots \), which

1. verifies \( a_0 \not\geq a_i \) for all \( i > 0 \),

2. is itself a bad sequence—otherwise the full sequence \( a_0, a_1, a_2, \ldots \) would be good,

3. is controlled by \((g, g(n))\)—otherwise the full sequence \( a_0, a_1, a_2, \ldots \) would not be \((g, n)\)-controlled.

Item 1 motivates the following definition:

**Definition 2.9 (Residuals).** For a nwqo \( A \) and an element \( a \in A \), the residual nwqo \( A/a \) is the substructure (a nwqo) induced by the subset \( A/a \overset{\text{def}}{=} \{ a' \in A \mid a \not\geq a' \} \) of elements that are not above \( a \).

**Example 2.10 (Residuals).** For all \( l < k \) and \( i \in \{1, \ldots, k\} \):

\[
\mathbb{N}/l = [k]/l = [l], \quad \Gamma_k/a_i \equiv \Gamma_{k-1}.
\]  

(2.32)
The conditions[1–3] on the suffix sequence $a_1, a_2, \ldots$ show that it is a $(g, g(n))$-controlled bad sequence over $A/a_0$. Thus by choosing an $a'_0 \in A_{\leq n}$ that maximizes $L_{g,A/a'_0}(g(n))$ through some suffix sequence $a'_1, a'_2, \ldots$, we can construct a $(g, n)$-controlled bad sequence $a'_0, a'_1, a'_2, \ldots$ of length $1 + L_{g,A/a'_0}(g(n))$, which shows

$$L_{g,A}(n) \geq \max_{a \in A_{\leq n}} \{ 1 + L_{g,A/a}(g(n)) \} .$$

(2.33)

The converse inequality is easy to check: consider a maximal $(g, n)$-controlled bad sequence $a''_0, a''_1, \ldots$ over $A$, thus of length $L_{g,A}(n)$. If this sequence is not empty, i.e. if $L_{g,A}(n) > 0$, then $a'_0 \in A_{\leq n}$ and its suffix $a''_1, a''_2, \ldots$ is of length $L_{g,A/a''_1}(g(n))$—or we could substitute a longer suffix. Hence:

**Proposition 2.11 (Descent Equation).**

$$L_{g,A}(n) = \max_{a \in A_{\leq n}} \{ 1 + L_{g,A/a}(g(n)) \} .$$

(2.34)

This reduces the $L_{g,A}$ function to a finite combination of $L_{g,A_i}$’s where the $A_i$’s are residuals of $A$, hence “smaller” sets. Residuation is well-founded for nwoqs: a sequence of successive residuals $A \supset A/a_0 \supset A/a_0/a_1 \supset \cdots$ is necessarily finite since $a_0, a_1, \ldots$ must be a bad sequence. Hence the recursion in the **Descent Equation** is well-founded and can be used to evaluate $L_{g,A}(n)$. This is our starting point for analyzing the behaviour of length functions.

**Example 2.12.** Let us consider the case of $L_{g,[k]}(n)$ for $k \leq n + 1$: by induction on $k$, we can see that

$$L_{g,[k]}(n) = k .$$

(2.35)

Indeed, this holds trivially for $[0] = \emptyset$, and for the induction step, it also holds for $k + 1 \leq n + 1$, since then $[k + 1]_{\leq n} = [k + 1]$ and thus by the **Descent Equation**

$$L_{g,[k+1]}(n) = \max_{l \in [k+1]} \{ 1 + L_{g,[k+1]/l}(g(n)) \}$$

$$= \max_{l \in [k+1]} \{ 1 + L_{g,[l]}(g(n)) \}$$

$$= \max_{l \in [k+1]} \{ 1 + l \}$$

$$= 1 + k$$

using (2.32) and the induction hypothesis on $l \leq k \leq n \leq g(n)$.

**Example 2.13.** Let us consider again the case of $L_{g,N}$: by the **Descent Equation**

$$L_{g,N}(n) = \max_{k \in N_{\leq n}} \{ 1 + L_{g,N/k}(g(n)) \}$$

$$= \max_{k \in N_{\leq n}} \{ 1 + L_{g,[k]}(g(n)) \}$$

$$= \max_{k \in N_{\leq n}} \{ 1 + k \}$$

$$= n$$
thanks to (2.32) and (2.35) on \( k \leq n \).

### 2.3.2 Reflecting nwqos

The reader might have noticed that Example 2.13 does not quite follow the reasoning that led to (2.29) on page 34; although we started by decomposing bad sequences into a first element and a suffix as in the Descent Equation, we rather used (2.31) to treat the suffix by seeing it as a bad sequence over \( \Gamma_n \) and to deduce the value of \( L_{g,\mathbb{N}}(n) \). However, as already mentioned in Example 2.3 on page 29, \( \Gamma_n \neq [n] \) in general.

We can reconcile the analyses made for (2.29) on page 34 and in Example 2.13 by noticing that bad sequences are never shorter in \( n \) than in \([n]\). We will prove this formally using reflections, which let us simplify instances of the Descent Equation by replacing all \( A/a \) for \( a \in A_{\leq n} \) by a single (or a few) \( A' \) that is larger than any of the considered \( A/a \)'s—but still reasonably small compared to \( A \), so that a well-founded inductive reasoning remains possible.

**Definition 2.14.** A nwqo reflection is a mapping \( h: A \to B \) between two nwqos that satisfies the two following properties:

\[
\forall a, a' \in A : h(a) \leq_B h(a') \text{ implies } a \leq_A a', \tag{2.36}
\]

\[
\forall a \in A : |h(a)|_B \leq |a|_A . \tag{2.37}
\]

In other words, a nwqo reflection is an order reflection that is also norm-decreasing (not necessarily strictly).

We write \( h: A \leftarrow B \) when \( h \) is a nwqo reflection and say that \( B \) reflects \( A \). This induces a relation between nwqos, written \( A \leftarrow B \).

Reflection is transitive since \( h: A \leftarrow B \) and \( h': B \leftarrow C \) entails \( h' \circ h: A \leftarrow C \). It is also reflexive, hence reflection is a quasi-ordering. Any nwqo reflects its induced substructures since \( \text{Id}: X \leftarrow X \) when \( X \) is a substructure of \( A \). Thus \( \Gamma_0 \leftarrow A \) for any \( A \), and \( \Gamma_1 \leftarrow A \) for any non-empty \( A \).

**Example 2.15** (Reflections). Among the basic nwqos from Example 2.3, we note the following relations (or absences thereof). For any \( k \in \mathbb{N} \), \([k] \leftarrow \Gamma_k\), while \( \Gamma_k \not\rightarrow [k] \) when \( k \geq 2 \). The reflection of induced substructures yields \([k] \leftarrow \mathbb{N}\) and \( \Gamma_k \leftarrow \Gamma_{k+1} \). Obviously, \( \mathbb{N} \not\leftrightarrow [k] \) and \( \Gamma_{k+1} \not\rightarrow \Gamma_k \).

Reflections preserve controlled bad sequences. Let \( h: A \leftarrow B \), consider a sequence \( s = a_0, a_1, \ldots \) over \( A \), and write \( h(s) \) for \( h(a_0), h(a_1), \ldots \), a sequence over \( B \). Then by (2.36), \( h(s) \) is bad when \( s \) is, and by (2.37), it is \((g, n)\)-controlled when \( s \) is. Hence we can complete the picture of the monotonicity properties of \( L \) started in Remark 2.2 on page 28:

**Proposition 2.16** (Monotonicity of \( L \) in \( A \)).

\[
A \leftarrow B \text{ implies } L_{g,A}(n) \leq L_{g,B}(n) \text{ for all } g, n . \tag{2.38}
\]
2.3. Bounding the Length Function

This is the last missing piece for deducing (2.29) from (2.31): since \([k] \hookrightarrow \Gamma_k\), \(L_{g,[k]}(n) \leq L_{g,\Gamma_k}(n)\) by Proposition 2.16—the converse inequality holds for \(k \leq n + 1\), as seen with (2.31) and (2.35), but not for \(k > n + 1\) as seen in Example 2.3.

**Remark 2.17 (Reflection is a Precongruence).** Reflections are compatible with product and sum:

\[ A \leftrightarrow A' \text{ and } B \leftrightarrow B' \text{ imply } A + B \leftrightarrow A' + B' \text{ and } A \times B \leftrightarrow A' \times B' . \]  

\[ (2.39) \]

**Inductive Residual Computations.** We may now tackle our first main problem: computing residuals \(A/a\). The Descent Equation, though it offers a powerful way of computing the length function, can very quickly lead to complex expressions, as the nwqos \(A/a_0/a_1/\cdots/a_n\) become “unstructured”, i.e. have no nice definition in terms of + and ×. Residuation allows us to approximate these sets, so that the computation can be carried out without leaving the realm of polynomial nwqos, leading to an *inductive* computation of \(A/a\) over the structure of the polynomial nwqo \(A\).

The base cases of this induction were already provided as (2.32) for finite sets \(\Gamma_k\), and

\[ \mathbb{N}/k \leftrightarrow \Gamma_k \]  

\[ (2.40) \]

for the naturals \(\mathbb{N}\)—because \(\mathbb{N}/k = [k]\) by (2.32), and then \([k] \hookrightarrow \Gamma_k\) as seen in Example 2.15, which was implicit in the computation of \(L_{g,\mathbb{N}}\) in (2.29). Regarding disjoint sums \(A + B\), it is plain that

\[ (A + B)/\langle 1, a \rangle = (A/a) + B , \quad (A + B)/\langle 2, b \rangle = A + (B/b) , \]  

\[ (2.41) \]

and reflections are not required.

The case of cartesian products \(A \times B\) is different: Let \(g(x) = 2x\) and consider the following \((g, 3)\)-controlled bad sequence over \(\mathbb{N}^2\)

\[ \langle 3, 2 \rangle , \, \langle 5, 1 \rangle , \, \langle 0, 4 \rangle , \, \langle 17, 0 \rangle , \, \langle 1, 1 \rangle , \, \langle 16, 0 \rangle , \, \langle 0, 3 \rangle . \]  

\[ (2.42) \]

Our purpose is to reflect \(\mathbb{N}^2/\langle 3, 2 \rangle\) into a simpler polynomial nwqo. The main intuition is that, for each tuple \(\langle a, b \rangle\) in the suffix, \(\langle 3, 2 \rangle \not\subseteq \langle a, b \rangle\) entails that

---

**Figure 2.3:** The elements of the bad sequence (2.42) and the two regions for the decomposition of \(\mathbb{N}^2/\langle 3, 2 \rangle\).
3 ≤ a or 2 ≤ b. Thus we can partition the elements of this suffix into two groups: the pairs where the first coordinate is in \( \mathbb{N}/3 \), and the pairs where the second coordinate is in \( \mathbb{N}/2 \)—an element might fulfill both conditions, in which case we choose an arbitrary group for it. Thus the elements of the suffix can be either from \( (\mathbb{N}/3) \times \mathbb{N} \) or from \( \mathbb{N} \times (\mathbb{N}/2) \), and the whole suffix can be reflected into their disjoint sum \( (\mathbb{N}/3) \times \mathbb{N} + \mathbb{N} \times (\mathbb{N}/2) \).

For our example (2.42), we obtain the decomposition (see also Figure 2.3)

\[
\langle 3, 2 \rangle, \{ \langle 5, 1 \rangle, \ldots, \langle 17, 0 \rangle, \langle 1, 1 \rangle, \langle 16, 0 \rangle, \ldots, \langle 0, 4 \rangle, \ldots, \langle 0, 3 \rangle \in (\mathbb{N}/3) \times \mathbb{N} \}
\]

(2.43)

We could have put \( \langle 1, 1 \rangle \) in either \( \mathbb{N} \times (\mathbb{N}/2) \) or \( (\mathbb{N}/3) \times \mathbb{N} \) but we had no choice for the other elements of the suffix. Observe that the two subsequences \( \{ \langle 0, 4 \rangle, \ldots, \langle 0, 3 \rangle \} \) and \( \{ \langle 5, 1 \rangle, \langle 17, 0 \rangle, \langle 1, 1 \rangle, \langle 16, 0 \rangle \} \) are indeed bad, but not necessarily \((g, g(3))-controlled: |\langle 17, 0 \rangle| = 17 ≥ 12 = g(g(3))\). However, we do not see them as independent sequences but consider their disjoint sum instead, so that their elements inherit their positions from the original sequence, and indeed the suffix sequence in (2.43) is \((g, g(3))-controlled.

By a straightforward generalization of the argument:

\[
(A \times B)/\langle a, b \rangle \leftrightarrow ((A/a) \times B) + (A \times (B/b))
\]

(2.44)

Since it provides reflections instead of isomorphisms, (2.44) is not meant to support exact computations of \( A/a \) by induction over the structure of \( A \) (see Exercise 2.5). More to the point, it yields over-approximations that are sufficiently precise for our purposes while bringing important simplifications when we have to reflect the \( A/a \) for all \( a \in A_{\leq n} \).

### 2.3.3 A Bounding Function

It is time to wrap up our analysis of \( L \). We first combine the inductive residuation and reflection operations into derivation relations \( \partial_n \): intuitively, the relation \( A \partial_n A' \) is included in the relation \( “ A/a \leftrightarrow A' “ \) for some \( a \in A_{\leq n} \) (see Lemma 2.19 for the formal statement). More to the point, the derivation relation captures a particular way of reflecting residuals, which enjoys some good properties: for every \( n \), given \( A \) a nwqo in polynomial normal form (recall Remark 2.7 on page 30), \( \partial_n A \) is a finite set of polynomial nwqos also in PNF, defined inductively by

\[
\partial_n 0 \overset{\text{df}}{=} \emptyset,
\]

(2.45)

\[
\partial_n \mathbb{N}^0 \overset{\text{df}}{=} \{ 0 \},
\]

(2.46)

\[
\partial_n \mathbb{N}^d \overset{\text{df}}{=} \{ \mathbb{N}^{d-1} \cdot nd \},
\]

(2.47)

\[
\partial_n (A + B) \overset{\text{df}}{=} (\partial_n A + B) \cup (A + (\partial_n B)),
\]

(2.48)
for \( d > 0 \) and \( A, B \) in PNF; in these definitions the + operations are lifted to act upon nwqo sets \( S \) by \( A + S \overset{def}{=} \{ A + A' \mid A' \in S \} \) and symmetrically. Note that (2.46) can be seen as a particular case of (2.47) if we ignore the undefined \( \mathbb{N}^{0-1} \) and focus on its coefficient 0.

An important fact that will become apparent in the next section is

**Fact 2.18 (Well-Foundedness).** The relation \( \partial \overset{def}{=} \bigcup_n \partial_n \) is well-founded.

The definition of \( \partial_n \) verifies:

**Lemma 2.19.** Let \( A \) be a polynomial nwqo in PNF and \( a \in A_{\leq n} \) for some \( n \). Then there exists \( A' \) in \( \partial_n A \) s.t. \( A/a \hookrightarrow A' \).

**Proof.** Let \( A \equiv \mathbb{N}^{d_1} + \cdots + \mathbb{N}^{d_m} \) in PNF and let \( a \in A_{\leq n} \) for some \( n \); note that the existence of \( a \) rules out the case of \( m = 0 \) (i.e. \( A \equiv \Gamma_0 \)), thus (2.45) vacuously verifies the lemma.

We proceed by induction on \( m > 0 \): the base case is \( m = 1 \), i.e. \( A \equiv \mathbb{N}^{d_1} \), and perform a nested induction on \( d \): if \( d = 0 \), then \( A \equiv \Gamma_1 \), thus \( A/a \equiv \Gamma_0 \) by (2.32); this is in accordance with (2.46), and the lemma holds. If \( d = 1 \), i.e. \( A \equiv \mathbb{N} \), then \( A/a \hookrightarrow \Gamma_a \) by (2.40), and then \( \Gamma_a \hookrightarrow \Gamma_n \equiv \mathbb{N}^0 \cdot n \) as seen in Example 2.15 since \( a \leq n \), thus (2.47) verifies the lemma. For the induction step on \( d > 1 \),

\[
A \equiv \mathbb{N}^d = \mathbb{N} \times \mathbb{N}^{d-1}
\]

and thus \( a = (k, b) \) for some \( k \in \mathbb{N}_{\leq n} \) and \( b \in \mathbb{N}^{d-1}_{\leq n} \). By (2.44),

\[
A/a \hookrightarrow \left( (\mathbb{N}/k) \times \mathbb{N}^{d-1} \right) + (\mathbb{N} \times (\mathbb{N}^{d-1}/b))
\]

Using the ind. hyp. on \( \mathbb{N}/k \) along with Remark 2.17,

\[
\hookrightarrow \left( (\mathbb{N}^0 \cdot n) \times \mathbb{N}^{d-1} \right) + (\mathbb{N} \times (\mathbb{N}^{d-1}/b))
\]

\[
\equiv (\mathbb{N}^{d-1} \cdot n) + (\mathbb{N} \times (\mathbb{N}^{d-1}/b))
\]

Using the ind. hyp. on \( \mathbb{N}/b \) along with Remark 2.17,

\[
\hookrightarrow (\mathbb{N}^{d-1} \cdot n) + (\mathbb{N} \times (\mathbb{N}^{d-2} \cdot n(d-1)))
\]

\[
\equiv \mathbb{N}^{d-1} \cdot nd,
\]

in accordance with (2.47).

For the induction step on \( m > 1 \), i.e. if \( A \equiv B + C \), then wlog. \( a = (1, b) \) for some \( b \in B_{\leq n} \) and thus by (2.41) \( A/a = (B/b) + C \). By ind. hyp., there exists \( B' \in \partial_n B \) s.t. \( B/b \hookrightarrow B' \), thus \( A/a \hookrightarrow B' + C \) by Remark 2.17, the latter nwqo being in \( \partial_n A \) according to (2.48).

The computation of derivatives can be simplified by replacing (2.45) and (2.48) by a single equation (see Exercise 2.6):

\[
\partial_n A = \left\{ B + \partial_n \mathbb{N}^d \mid A \equiv B + \mathbb{N}^d, d \geq 0 \right\}.
\] (2.49)
THE BOUNDING FUNCTION $M_{g,A}$ for $A$ a polynomial nwqo in PNF is defined by

$$M_{g,A}(n) \overset{\text{def}}{=} \max_{A' \in \partial_n A} \left\{ 1 + M_{g,A'}(g(n)) \right\}.$$  \hfill (2.50)

This function $M$ is well-defined as a consequence of Fact 2.18 and of the finiteness of $\partial_n A$ for all $n$ and $A$; its main property is

Proposition 2.20. For any polynomial nwqo $A$ in PNF, any control function $g$, and any initial control $n$,

$$L_{g,A}(n) \leq M_{g,A}(n).$$  \hfill (2.51)

Proof. Either $A \leq n$ is empty and then $L_{g,A}(n) = 0 \leq M_{g,A}(n)$, or there exists some $a \in A \leq n$ that maximizes $L_{g,A/a}(g(n))$ in the Descent Equation, i.e.

$$L_{g,A}(n) = 1 + L_{g,A/a}(g(n)).$$

By Lemma 2.19 there exists $A' \in \partial_n A$ s.t. $A/a \leftrightarrow A'$, thus by Proposition 2.16

$$L_{g,A}(n) \leq 1 + L_{g,A'}(g(n)).$$

By well-founded induction on $A' \in \partial_n A$, $L_{g,A'}(g(n)) \leq M_{g,A'}(g(n))$, thus

$$L_{g,A}(n) \leq 1 + M_{g,A'}(g(n)) \leq M_{g,A}(n)$$

by definition of $M$. \hfill $\square$

2.4 \textit{Classification in the Grzegorczyk Hierarchy}

Now equipped with a suitable bound $M_{g,A}(n)$ on the length of $(g, n)$-controlled bad sequences over $A$, the only remaining issue is its classification inside the Grzegorczyk hierarchy. We first exhibit a very nice isomorphism between polynomial nwqos (seen up to isomorphism) and their \textit{maximal order types}, which are ordinals below $\omega^\omega$.

2.4.1 \textit{Maximal Order Types}

Consider a wqo $(A, \leq)$; it defines an associated strict ordering $< \overset{\text{def}}{=} \{(a, a') \in A^2 \mid a \leq a' \text{ and } a' \nleq a\}$. There are many possible linearizations $< \overset{\text{def}}{=} \prec$, i.e. linear orders with $< \subseteq \prec$, obtained by equating equivalent elements and “orienting” the pairs of incomparable elements $(a, a')$ of $(A, \leq)$. Each of these linearizations is a well-ordering and is thus isomorphic to some ordinal, called its \textit{order type}, that intuitively captures its “length.” The \textit{maximal order type} of $(A, \leq)$ is then defined as the maximal such order type over all the possible linearizations; it provides a measure of the complexity of the (n)wqo.

Example 2.21 (Maximal Order Types). In a finite set $\Gamma_k$, the strict ordering is empty and the $k!$ different linear orders over $\Gamma_k$ are all of order type $k$. In an initial
segment of the naturals \([k]\) (respectively in the naturals \(\mathbb{N}\)), the only linearization is the natural ordering \(<\) itself, which is of order type \(k\) (respectively \(\omega\)):

\[
o(\Gamma_k) = o([k]) = k, \quad o(\mathbb{N}) = \omega.
\] (2.52)

**Remark 2.22.** By definition of the maximal order type of a nwqo \(A\), if \(A \equiv A'\) then \(o(A) = o(A')\).

As seen with our example, the maximal order type of a polynomial nwqo is not necessarily finite, which prompts us to recall a few elements of ordinal notations.

**Ordinal Terms.** Let \(\varepsilon_0\) be the supremum of the family of ordinals \(\{0, 1, \omega, \omega^\omega, \omega^{\omega^\omega}, \ldots\}\) (in other words \(\varepsilon_0\) is the smallest solution of the equation \(\omega^x = x\)). It is well-known that ordinals below \(\varepsilon_0\) can be written down in a canonical way as ordinal terms in Cantor Normal Form (CNF), i.e. sums

\[
\alpha = \omega^{\beta_1} + \cdots + \omega^{\beta_m} = \sum_{i=1}^{m} \omega^{\beta_i}
\] (2.53)

with \(\alpha > \beta_1 \geq \cdots \geq \beta_m \geq 0\) and each \(\beta_i\) itself a term in CNF. We write 1 for \(\omega^0\) and \(\alpha \cdot n\) for \(\alpha + \cdots + \alpha\). Recall that the direct sum operator \(+\) is associative \(((\alpha + \beta) + \gamma = \alpha + (\beta + \gamma))\) and idempotent \((\alpha + 0 = \alpha = 0 + \alpha)\) but not commutative (e.g. \(1 + \omega = \omega \neq \omega + 1\)). An ordinal term \(\alpha\) of form \(\gamma + 1\) is called a successor ordinal. Otherwise, if not 0, it is a limit ordinal, usually denoted \(\lambda\). We write \(\text{CNF}(\alpha)\) for the set of ordinal terms \(\alpha' < \alpha\) in CNF (which is in bijection with the ordinal \(\alpha\), and we use ordinal terms in CNF and set-theoretic ordinals interchangeably).

Also recall the definitions of the natural sum \(\alpha \oplus \alpha'\) and natural product \(\alpha \otimes \alpha'\) of two terms in CNF:

\[
\sum_{i=1}^{m} \omega^{\beta_i} \oplus \sum_{j=1}^{n} \omega^{\beta'_j} = \sum_{k=1}^{m+n} \omega^{\gamma_k}, \quad \sum_{i=1}^{m} \omega^{\beta_i} \otimes \sum_{j=1}^{n} \omega^{\beta'_j} = \bigoplus_{i=1}^{m} \bigoplus_{j=1}^{n} \omega^{\beta_i \oplus \beta'_j}, \tag{2.54}
\]

where \(\gamma_1 \geq \cdots \geq \gamma_{m+n}\) is a reordering of \(\beta_1, \ldots, \beta_m, \beta'_1, \ldots, \beta'_n\).

**Maximal Order Types.** We map polynomial nwqos \((A, \leq, \cdot, |A|)\) to ordinals in \(\omega^\omega\) using the maximal order type \(o(A)\) of the underlying wqo \((A, \leq)\). Formally, \(o(A)\) can be computed inductively using (2.52) and the following characterization:

**Fact 2.23.** For any wqos \(A\) and \(B\)

\[
o(A + B) = o(A) \oplus o(B), \quad o(A \times B) = o(A) \otimes o(B). \tag{2.55}
\]

**Example 2.24.** Given a polynomial nwqo in PNF \(A \equiv \sum_{i=1}^{m} \mathbb{N}^{d_i}\), its associated maximal order type is \(o(A) = \bigoplus_{i=1}^{m} \omega^{d_i}\), which is in \(\omega^\omega\). It turns out that \(o\) is a bijection between polynomial nwqos and \(\omega^\omega\) (see Exercise 2.7).
It is more convenient to reason with ordinal arithmetic rather than with polynomial nwqos, and we lift the definitions of $\partial$ and $M$ to ordinals in $\omega^\omega$. Define for all $\alpha$ in $\omega^\omega$ and all $d, n \in \mathbb{N}$

$$\partial_n\omega^d \overset{\text{def}}{=} \begin{cases} 0 & \text{if } d = 0 \\ \omega^{d-1} \cdot (nd) & \text{otherwise} \end{cases} \quad (2.56)$$

$$\partial_n\alpha \overset{\text{def}}{=} \{ \gamma \oplus \partial_n\omega^d \mid \alpha = \gamma \oplus \omega^d \} \quad (2.57)$$

$$M_{g,\alpha}(n) \overset{\text{def}}{=} \max_{\alpha' \in \partial_n\alpha} \left\{ 1 + M_{g,\alpha'}(g(n)) \right\} \quad (2.58)$$

Equation (2.56) restates (2.46) and (2.47) using maximal order types, while (2.57) and (2.58) mirror respectively (2.49) and (2.50) but work in $\omega^\omega$; one easily obtains the following slight variation of Proposition 2.20:

**Corollary 2.25.** For any polynomial nwqo $A$, any control function $g$, and any initial control $n$,

$$L_{g,A}(n) \leq M_{g,o(A)}(n) \quad (2.59)$$

A benefit of ordinal notations is that the well-foundedness of $\partial$ announced in Fact 2.18 is now an immediate consequence of $<$ being a well ordering: one can check that for any $n$, $\alpha' \in \partial_n\alpha$ implies $\alpha' < \alpha$ (see Exercise 2.8).

**Example 2.26.** One can check that

$$M_{g,k}(n) = k \quad M_{g,\omega}(n) = n + 1 \quad (2.60)$$

(Note that if $n > 0$ this matches $L_{g,\Gamma_k}(n)$ exactly by (2.31)). This follows from

$$\partial_n k = \begin{cases} \emptyset & \text{if } k = 0 \\ \{k - 1\} & \text{otherwise} \end{cases} \quad \partial_n \omega = n \quad (2.61)$$

### 2.4.2 The Cichon Hierarchy

A second benefit of working with ordinal indices is that we can exercise a richer theory of subrecursive hierarchies, for which many results are known. Let us first introduce the basic concepts.

**Fundamental Sequences.** Subrecursive hierarchies are defined through assignments of *fundamental sequences* $(\lambda_x)_{x < \omega}$ for limit ordinal terms $\lambda$, verifying $\lambda_x < \lambda$ for all $x$ and $\lambda = \sup_x \lambda_x$. The usual way to obtain families of fundamental sequences is to fix a particular sequence $\omega_x$ for $\omega$ and to define on ordinal terms in CNF

$$(\gamma + \omega^{\beta+1})_x \overset{\text{def}}{=} \gamma + \omega^\beta \cdot \omega_x, \quad (\gamma + \omega^\lambda)_x \overset{\text{def}}{=} \gamma + \omega^{\lambda_x} \quad (2.62)$$

We always assume the standard assignment $\omega_x \overset{\text{def}}{=} x + 1$ in the remainder of the chapter. Note that this assignment implies $\lambda_x > 0$ for all $x$. 

---

*Note:* The content includes mathematical notation and definitions, formatted in LaTeX. The text is a continuation of the discussion on complexity upper bounds, focusing on ordinal arithmetic and its application to polynomial nwqos. It introduces definitions and theorems, including corollaries and examples, to illustrate the concepts. The section concludes with remarks on subrecursive hierarchies and their applications. The document emphasizes the convenience of reasoning with ordinal arithmetic and the well-foundedness of the partial order $\partial$. It also mentions the Cichon hierarchy, a rich theory of subrecursive hierarchies, and introduces fundamental sequences for limit ordinal terms.
PREDECESSORS. Given an assignment of fundamental sequences, one defines the 
\((x\text{-indexed})\) predecessor \(P_x(\alpha) < \alpha\) of an ordinal \(\alpha \neq 0\) as
\[
P_x(\alpha + 1) \overset{\text{def}}{=} \alpha, \quad P_x(\lambda) \overset{\text{def}}{=} P_x(\lambda_x).
\] (2.63)

Thus in all cases \(P_x(\alpha) < \alpha\) since \(\lambda_x < \lambda\). One can check that for all \(\alpha > 0\) and \(x\) (see Exercise 2.9)
\[
P_x(\gamma + \alpha) = \gamma + P_x(\alpha). \tag{2.64}
\]

Observe that predecessors of ordinals in \(\omega^\omega\) are very similar to our derivatives: for \(d = 0\), \(P_0(\omega^d) = 0\) and otherwise \(P_0(\omega^d) = \omega^{d-1} \cdot n + P_0(\omega^{d-1})\), which is somewhat similar to (2.56), and more generally (2.64) is reminiscent of (2.57) but chooses a particular strategy: always derive the \(\omega^d\) summand with the smallest \(d\). The relationship will be made more precise in Section 2.4.3 on the following page.

THE CICHÓŃ HIERARCHY. Fix a unary function \(h: \mathbb{N} \to \mathbb{N}\). We define the Cichoń hierarchy \((h_\alpha)_{\alpha \in \varepsilon_0}\) by
\[
h_0(x) \overset{\text{def}}{=} 0, \quad h_{\alpha+1}(x) \overset{\text{def}}{=} 1 + h_\alpha(h(x)), \quad h_\lambda(x) \overset{\text{def}}{=} h_{\lambda_x}(x). \tag{2.65}
\]

In the initial segment \(\omega^\omega\), this hierarchy is closely related to \((M_{g,\alpha})_{\alpha \in \omega^\omega}\) indeed, we already noted the similarities between \(P_0(\alpha)\) and \(\partial_n \alpha\), and furthermore

**Lemma 2.27.** For all \(\alpha > 0\) in \(\varepsilon_0\) and \(x\),
\[
h_\alpha(x) = 1 + h_{P_x(\alpha)}(h(x)). \tag{2.66}
\]

**Proof.** By transfinite induction over \(\alpha > 0\). For a successor ordinal \(\alpha' + 1\), 
\[h_{\alpha' + 1}(x) = 1 + h_{\alpha'}(h(x)) = 1 + h_{P_x(\alpha' + 1)}(h(x)).\]
For a limit ordinal \(\lambda\), \(h_\lambda(x) = h_{\lambda_x}(x)\) is equal to \(1 + h_{P_x(\lambda_x)}(h(x))\) by ind. hyp. since \(0 < \lambda_x < \lambda\), which is the same as \(1 + h_{P_x(\lambda)}(h(x))\) by definition of \(P_x(\lambda)\). \hfill \Box

**Example 2.28 (Cichoń Hierarchy).** First note that \(h_k(x) = k\) for all \(k < \omega, x,\) and \(h\). This can be shown by induction on \(k\): it holds for the base case \(k = 0\) by definition, and also for the induction step as \(h_{k+1}(x) = 1 + h_k(h(x)) = 1 + k\) by induction hypothesis. Therefore \(h_\omega(x) = h_{x+1}(x) = x + 1\) regardless of the choice of \(h\).

For ordinals greater than \(\omega\), the choice of \(h\) becomes significant. Setting \(H(x) \overset{\text{def}}{=} x + 1\), we obtain a particular hierarchy \((H_\alpha)\) that verifies for instance
\[
H_{\omega \cdot 2}(x) = H_{\omega \cdot x + 1}(x) = H_\omega(2x + 1) + x = 3x + 1, \tag{2.67}
\]
\[
H_{\omega^2}(x) = (2x + 1)(x + 1). \tag{2.68}
\]

The functions in the Cichoń hierarchy enjoy many more properties, of which we will use the following two:
Fact 2.29 (Argument Monotonicity). If \( h \) is monotone, then each \( h_\alpha \) function is also monotone in its argument: if \( x \leq x' \) then \( h_\alpha(x) \leq h_\alpha(x') \).

Fact 2.30 (Classification in the Grzegorczyk Hierarchy). Let \( 0 < \gamma < \omega \). If \( h \) is bounded by a function in \( \mathcal{F}_\gamma \) and \( \alpha < \omega^{d+1} \), then \( h_\alpha \) is bounded by a function in \( \mathcal{F}_{\gamma+d} \).

### 2.4.3 Monotonicity

One obstacle subsists before we can finally prove the Length Function Theorem: the functions \( M_{g,\alpha} \) and \( h_\alpha \) are not monotone in the parameter \( \alpha \). Indeed, \( \alpha' < \alpha \) does not imply \( M_{g,\alpha'}(n) \leq M_{g,\alpha}(n) \) for all \( n \): witness the case \( \alpha = \omega \) and \( \alpha' = n+2 \): \( M_{g,\omega}(n) = 1 + M_{g,n}(g(n)) = 1 + n \) but \( M_{g,n+2}(n) = n+2 \) by Example 2.26.

Similarly with \( h_\alpha \), as seen with Example 2.28, \( h_{x+2}(x) = x+2 > x+1 = h_\omega(x) \), although \( x+2 < \omega \).

In our case a rather simple ordering is sufficient: we define a structural ordering \( \sqsubseteq \) for ordinals in \( \omega^\omega \) by

\[
\omega^{d_1} + \cdots + \omega^{d_m} \sqsubseteq \omega^{d'_1} + \cdots + \omega^{d'_n} \iff m \leq n \text{ and } \forall 1 \leq i \leq m, \ d_i \leq d'_i
\]  

for ordinal terms in \( \text{CNF}(\omega^\omega) \), i.e. \( \omega > d_1 \geq \cdots \geq d_m \geq 0 \) and \( \omega > d'_1 \geq \cdots \geq d'_n \geq 0 \). A useful observation is that \( \sqsubseteq \) is a precongruence for \( \oplus \) (see Exercise 2.10):

\[
\alpha \sqsubseteq \alpha' \text{ and } \gamma \sqsubseteq \gamma' \implies \alpha \oplus \gamma \sqsubseteq \alpha' \oplus \gamma'.
\]  

The structural ordering rules out the previous examples, as \( x+2 \not\sqsubseteq \omega \) for any \( x \). This refined ordering yields the desired monotonicity property for \( M \)—see Lemma 2.31 next (it can also be proven for \( h \); see Exercise 2.11)—but let us first introduce some notation: we write \( \alpha' = \partial_{d,n,\alpha} \) if \( \alpha = \gamma \oplus \omega^d \) and \( \alpha' = \gamma \oplus \partial_{n,\omega^d} \).

Then (2.58) can be rewritten as

\[
M_{g,\alpha}(n) = \max_{\alpha = \gamma \oplus \omega^d} \left\{ 1 + M_{g,\partial_{d,n,\alpha}}(g(n)) \right\}.
\]  

#### Lemma 2.31 (Structural Monotonicity).

Let \( \alpha, \alpha' \) be in \( \omega^\omega \) and \( x > 0 \). If \( \alpha \sqsubseteq \alpha' \), then \( M_{g,\alpha}(x) \leq M_{g,\alpha'}(x) \).

**Proof.** Let us proceed by induction. If \( \alpha = 0 \), then \( M_{g,\alpha}(x) = 0 \) and the lemma holds vacuously. Otherwise, for the induction step, write \( \alpha = \sum_{i=1}^m \omega^{d_i} \) and \( \alpha' = \sum_{j=1}^n \omega^{d_j} \); there is some maximizing index \( 1 \leq i \leq m \leq n \) such that

\[
M_{g,\alpha}(x) = 1 + M_{g,\partial_{d_i,x,\alpha}}(g(x)).
\]
As \( i \leq n \) and \( d_i \leq d'_i \), observe that \( \partial_{d_i,x}\alpha \subseteq \partial_{d'_i,x}\alpha' \), and by Fact 2.18, we can apply the induction hypothesis:

\[
M_{g,\alpha}(x) \leq 1 + M_{g,\partial_{d'_i,x}\alpha'}(g(x)) \\
\leq M_{g,\alpha'}(x). \quad \square
\]

An important consequence of Lemma 2.31 is that there is a maximizing strategy for \( M \), which is to always derive along the smallest term:

**Lemma 2.32 (Maximizing Strategy).** If \( \alpha = \gamma + \omega^d \) for some \( d \geq 0 \), then

\[
M_{g,\alpha}(n) = 1 + M_{g,\gamma + \partial_n\omega^d}(g(n)). 
\]  

(2.72)

**Proof.** Let \( \alpha = \gamma \oplus \omega^{d'} \oplus \omega^d \). We claim that if \( d \leq d' \) and \( n \leq n' \), then

\[
\partial_{d,n'}\partial_{d',n}\alpha \subseteq \partial_{d',n'}\partial_{d,n}\alpha . 
\]  

(2.73)

The lemma follows immediately from the claim, Lemma 2.31, and the fact that \( g \) is increasing.

The claim itself is easy to check using (2.70): abusing notations for the cases of \( d = 0 \) or \( d' = 0 \),

\[
\partial_{d,n'}\partial_{d',n}\alpha = \gamma \oplus (\omega^{d'-1} \cdot nd' + \omega^{d-1} \cdot n'd) \\
\partial_{d',n'}\partial_{d,n}\alpha = \gamma \oplus (\omega^{d'-1} \cdot n'd' + \omega^{d-1} \cdot nd) .
\]

Observe that \( nd' + nd' \leq n'd' + nd \), i.e. that the second line has at least as many terms as the first line, and thus fulfills the first condition of the structural ordering in (2.69). Furthermore, it has at least as many \( \omega^{d'-1} \) terms, thus fulfilling the second condition of (2.69). \( \square \)

Let us conclude with a comparison between derivatives and predecessors:

**Corollary 2.33.** If \( 0 < \alpha < \omega^{d+1} \), then \( M_{g,\alpha}(n) \leq 1 + M_{g,P_{n\omega^d}(\alpha)}(g(n)) \).

**Proof.** Since \( 0 < \alpha < \omega^{d+1} \), it can be written in CNF as \( \alpha = \gamma + \omega^{d'} \) for some \( \gamma < \alpha \) and \( d' \leq d \). By Lemma 2.32, \( M_{g,\alpha}(n) = 1 + M_{g,\gamma + \partial_n\omega^{d'}}(g(n)) \). If \( d' = 0 \), i.e. \( \alpha = \gamma + 1 \), then

\[
\gamma + \partial_1 = P_{\omega^d}(\alpha) = \gamma
\]

and the statement holds. Otherwise, by (2.70)

\[
\gamma + \partial_n\omega^d = \gamma + \omega^{d'-1} \cdot nd' \\
\subseteq \gamma + \omega^{d'-1} \cdot nd + P_{\omega^d}(\omega^{d'-1}) \\
= P_{\omega^d}(\alpha) ,
\]

from which we deduce the result by Lemma 2.31. \( \square \)
2.4.4 Wrapping Up

We have now all the required ingredients for a proof of the [Length Function Theorem]. Let us start with a uniform upper bound on $M_{g,\alpha}$:

**Theorem 2.34** (Uniform Upper Bound). Let $d > 0$, $g$ be a control function and select a monotone function $h$ such that $h(x \cdot d) \geq g(x) \cdot d$ for all $x$. If $\alpha < \omega^{d+1}$, then

$$M_{g,\alpha}(n) \leq h_\alpha(nd) .$$

(2.74)

**Proof.** We proceed by induction on $\alpha$: if $\alpha = 0$, then $M_{g,\alpha}(n) = 0 \leq h_\alpha(nd)$ for all $n$. Otherwise, by Corollary 2.33,

$$M_{g,\alpha}(n) \leq 1 + M_{g, P_{nd}(\alpha)}(g(x)) .$$

Because $P_{nd}(\alpha) < \alpha$, we can apply the induction hypothesis:

$$M_{g,\alpha}(n) \leq 1 + h_{P_{nd}(\alpha)}(g(nd))$$

since $h(nd) \geq g(nd)$ and $h_{P_{nd}(\alpha)}$ is monotone by Fact 2.29. Finally, by Lemma 2.27,

$$M_{g,\alpha}(n) \leq h_\alpha(nd) .$$

For instance, for $\alpha = \omega$, (and thus $d = 1$), we can choose $h = g$, and Theorem 2.34 yields that

$$M_{g,\omega}(n) \leq g_\omega(n) = n + 1 ,$$

(2.75)

which is optimal (recall examples 2.26 and 2.28).

Other examples where setting $h = g$ fits are $g(x) = 2x$, $g(x) = x^2$, $g(x) = 2^x$, etc. More generally, Theorem 2.34 can use $h = g$ if $g$ is super-homogeneous, i.e. if it verifies $g(dx) \geq g(x)d$ for all $d, x \geq 1$:

**Corollary 2.35.** Let $d > 0$, $g$ be a super-homogeneous control function, and $\alpha < \omega^{d+1}$. Then $L_{g,\alpha} \leq g_\alpha(nd)$.

We sometimes need to choose $h$ different from $g$: In a $d$-dimensional VASS with $p$ states, sequences of configurations are controlled by $g(x) = x + b$ for some maximal increment $b > 0$, and then $h(x) = x + db$ is also a suitable choice, which verifies

$$L_{g,\mathbb{N}^d \times \Gamma_p}(n) \leq M_{g,\omega^d \cdot p}(n) \leq h_{\omega^d \cdot p}(nd) \leq F_{d}^{\omega^d \cdot p}(nd) - nd ,$$

(2.76)

the latter being a function in $\mathcal{F}_d$ when $d, b, p$ are fixed according to (2.22):

**Corollary 2.36.** Let $g(x) = x + b$ for some $b > 0$, and fix $d, p \geq 0$. Then $L_{g,\mathbb{N}^d \times \Gamma_p}$ is bounded by a function in $\mathcal{F}_d$. 
Finally, we can choose a generic $h(x) = g(x)d$, as in the following proof of the Length Function Theorem:

**Theorem 2.8 (Length Function Theorem).** Let $g$ be a control function bounded by some function in $\mathcal{F}_\gamma$ for some $\gamma \geq 1$ and $d, p \geq 0$. Then $L_{g,N^d \times \Gamma_p}$ is bounded by a function in $\mathcal{F}_{\gamma+d}$.

**Proof.** Let $A \equiv N^d \times \Gamma_p$. The case of $d = 0$ is handled through (2.31), which shows that $L_{g,A}$ is a constant function in $\mathcal{F}_\gamma$.

For $d > 0$ we first use Corollary 2.25:

$$L_{g,A}(n) \leq M_{g,o(A)}(n). \quad (2.77)$$

Observe that $o(A) < \omega^{d+1}$, thus by Theorem 2.34

$$L_{g,A}(n) \leq h_{o(A)}(nd), \quad (2.78)$$

where $h(xd) = d \cdot g(xd) \geq d \cdot g(x)$ since $g$ is strictly monotone and $d > 0$. Because $h$ is defined from $g$ using linear operations, for all $\gamma \geq 1$, $g$ is bounded in $\mathcal{F}_\gamma$ if and only if $h$ is bounded in $\mathcal{F}_\gamma$, and thus by Fact 2.30 $L_{g,A}$ is bounded in $\mathcal{F}_{\gamma+d}$. □

How good are these upper bounds? We already noted that they were optimal for $N$ in (2.75), and the sequence (2.1) extracted from the successive configurations of simple was an example of a bad sequence with length function in $\mathcal{F}_3$. Exercise 2.15 generalizes simple to arbitrary dimensions $d$ and control functions $g$ and shows that a length $g_{\omega^d}(n)$ can be reached using the lexicographic ordering; this is very close to the upper bounds found for instance in (2.75) and Corollary 2.35. The next chapter will be devoted to complexity lower bounds, showing that for many decision problems, the enormous generic upper bounds we proved here are actually unavoidable.

**Exercises**

**Exercise 2.1 (Disjoint Sums).** Let $(A_1, \leq_{A_1})$ and $(A_2, \leq_{A_2})$ be two nwqos. Prove that $(A_1 + A_2, \leq_{A_1 + A_2})$ is a nwqo (see (2.5-2.7)).

**Exercise 2.2 (Fast-Growing Functions).**

(1) Show that $F_1(x) = 2x + 1$ and $F_2(x) = 2^{x+1}(x+1) - 1$ (stated in (2.20)). What are the values of $F_k(0)$ depending on $k$?

(2) Show that each fast-growing function is strictly expansive, i.e. that $F_k(x) > x$ for all $k$ and $x$.

(3) Show that each fast-growing function is strictly monotone in its argument, i.e. that for all $k$ and $x' > x$, $F_k(x') > F_k(x)$.
(4) Show that the fast-growing functions are strictly monotone in the parameter \( k \), more precisely that \( F_{k+1}(x) > F_k(x) \) for all \( k \), provided that \( x > 0 \).

**Exercise 2.3 (Grzegorczyk Hierarchy).** Each class \( \mathcal{F}_k \) of the Grzegorczyk hierarchy is formally defined as the closure of the constant zero function 0, the sum function \( +: x_1, x_2 \mapsto x_1 + x_2 \), the projections \( \pi_i^n: x_1, \ldots, x_n \mapsto x_i \) for all \( 0 < i \leq n \), and the fast-growing function \( F_k \), under two basic operations:

- **limited primitive recursion:*** if \( h_0, h_1, \ldots, h_p \) belong to the class, then so does \( f \) if
  \[
  f(x_1, \ldots, x_n) = h_0(h_1(x_1, \ldots, x_n), \ldots, h_p(x_1, \ldots, x_n)),
  \]
- **substitution:*** if \( h_0, h_1, \ldots, h_p \) belong to the class, then so does \( f \) if
  \[
  f(0, x_1, \ldots, x_n) = h_1(x_1, \ldots, x_n),
  f(y + 1, x_1, \ldots, x_n) = h_2(y, x_1, \ldots, x_n, f(y, x_1, \ldots, x_n)),
  f(y, x_1, \ldots, x_n) \leq h_3(y, x_1, \ldots, x_n).
  \]

Observe that *primitive recursion* is defined by ignoring the last *limitedness* condition in the previous definition.

(1) Define cut-off subtraction \( x \div y \) as \( x - y \) if \( x \geq y \) and 0 otherwise. Show that the following functions are in \( \mathcal{F}_0 \):
- predecessor: \( x \mapsto x \div 1 \),
- cut-off subtraction: \( x, y \mapsto x \div y \),
- odd: \( x \mapsto x \mod 2 \).

(2) Show that \( F_j \in \mathcal{F}_k \) for all \( j \leq k \).

(3) Show that, if a function \( f(x_1, \ldots, x_n) \) is linear, then it belongs to \( \mathcal{F}_0 \). Deduce that \( \mathcal{F}_0 = \mathcal{F}_1 \).

(4) Show that if a function \( f(x_1, \ldots, x_n) \) belongs to \( \mathcal{F}_k \) for \( k > 0 \), then there exists a constant \( c \in \mathbb{N} \) s.t. for all \( x_1, \ldots, x_n \), \( f(x_1, \ldots, x_n) < F_k^c(\max_i x_i + 1) \). Why does that fail for \( k = 0 \)?

(5) Deduce that \( F_{k+1} \) does not belong to \( \mathcal{F}_k \) for \( k > 0 \).

**Exercise 2.4 (Complexity of while Programs).** Consider a program like SIMPLE that consists of a loop with variables ranging over \( \mathbb{Z} \) and updates of linear complexity. Assume we obtain a \( k \)-ary disjunctive termination argument like (1.10) on page 8, where we synthesized linear ranking functions \( \rho_j \) into \( \mathbb{N} \) for each \( T_j \).

What can be told on the complexity of the program itself?

**Exercise 2.5 (Residuals of Cartesian Products).** For a nwqo \( A \) and an element \( a \in A \), define the nwqo \( \uparrow_A a \) (a substructure of \( A \)) by \( \uparrow_A a = \{ a' \in A \mid a \leq a' \} \). Thus \( A/a = A \setminus (\uparrow_A a) \). Prove the following:

\[
A \times B/(a,b) \neq (A/a \uplus B) + (A/a \times B/b) + (\uparrow_A a \times B/b),
\]

\[
(\forall) \quad A \times B/(a,b) \neq (A/a \times B) + (A \times B/b).
\]

(\*)
Exercise 2.6 (Derivatives). Prove \textbf{Equation (2.49)}: \[ \partial_n A = \{ B + \partial_n \mathbb{N}^d \mid A \equiv B + \mathbb{N}^d \} . \]

Exercise 2.7 (Maximal Order Types). The mapping from nwqos to their maximal order types is in general not a bijection (recall \( o(\Gamma_k) = o([k]) = k \) in \textbf{Example 2.21}). Prove that, if we restrict our attention to polynomial nwqos, then \( o \) is a bijection from polynomial nwqos (up to isomorphism) to CNF(\( \omega^\omega \)).

Exercise 2.8 (Well Foundedness of \( \partial \)). Recall that, when working with terms in CNF, the \textit{ordinal ordering} \( < \), which is a well ordering over ordinals, has a syntactic characterization akin to a lexicographic ordering:

\[
\sum_{i=1}^{m} \omega^{\beta_i} < \sum_{i=1}^{n} \omega^{\beta'_i} \iff \begin{cases} m < n \text{ and } \forall 1 \leq i \leq m, \beta_i = \beta'_i, \text{ or} \\ \exists 1 \leq j \leq \min(m, n), \beta_j < \beta'_j \text{ and } \forall 1 \leq i < j, \beta_i = \beta'_i . \end{cases} \tag{1}
\]

Prove \textbf{Fact 2.18}: The relation \( \partial \defeq \bigcup_n \partial_n \) is well-founded.

Exercise 2.9 (Predecessors). Prove \textbf{Equation (2.64)}: For all \( \alpha > 0 \), \( P_x (\gamma + \alpha) = \gamma + P_x (\alpha) \).

Exercise 2.10 (Structural Ordering). Prove \textbf{Equation (2.70)}: \( \sqsubseteq \) is a precongruence for \( \oplus \).

Exercise 2.11 (Structural Monotonicity). Let \( \alpha, \alpha' \) be in \( \omega^\omega \) and \( h \) be a strictly monotone unary function. Prove that, if \( \alpha \sqsubseteq \alpha' \), then \( h_\alpha (x) \leq h_{\alpha'} (x) \).

Exercise 2.12 (r-Bad Sequences). We consider in this exercise a generalization of good sequences: a sequence \( a_0, a_1, \ldots \) over a qo \( (A, \leq) \) is \( r \)-good if we can extract an increasing subsequence of length \( r + 1 \), i.e. if there exist \( r + 1 \) indices \( i_0 < \cdots < i_r \) s.t. \( a_{i_0} \leq \cdots \leq a_{i_r} \). A sequence is \( r \)-bad if it is not \( r \)-good. Thus “good” and “bad” stand for “1-good” and “1-bad” respectively.

By \textbf{wqo.2} (stated on page 11), \( r \)-bad sequences over a wqo \( A \) are always finite, and using the same arguments as in \textit{Section 2.1.1}, \( r \)-bad \( (g, n) \)-controlled sequences over a nwqo \( A \) have a maximal length \( L_{g,r,A}(n) \). Our purpose is to show that questions about the length of \( r \)-bad sequences reduce to questions about bad sequences:

\[
L_{g,r,A}(n) = L_{g,A \times \Gamma_r}(n) . \tag{3}
\]

(1) Show that such a maximal \( (g, n) \)-controlled \( r \)-bad sequence is \( (r - 1) \)-good.

(2) Given a sequence \( a_0, a_1, \ldots, a_r \) over a nwqo \( (A, \leq_A, \|A\|) \), an index \( i \) is \( p \)-good if it starts an increasing subsequence of length \( p + 1 \), i.e. if there exist indices \( i = i_0 < \cdots < i_p \) s.t. \( a_{i_0} \leq \cdots \leq a_{i_p} \). The \textit{goodness} \( \gamma(i) \) of an index \( i \) is the largest \( p \) s.t. \( i \) is \( p \)-good. Show that \( L_{g,r,A}(n) \leq L_{g,A \times \Gamma_r}(n) \).

(3) Show the converse, i.e. that \( L_{g,r,A}(n) \geq L_{g,A \times \Gamma_r}(n) \).

Exercise 2.13 (Hardy Hierarchy). A well-known variant of the Cichoń hierarchy is the \textit{Hardy hierarchy} \( (h^\alpha)_\alpha \) defined using a unary function \( h : \mathbb{N} \to \mathbb{N} \) by

\[
h^0 (x) \defeq x , \quad h^{\alpha+1} (x) \defeq h^\alpha (h(x)) , \quad h^\lambda (x) \defeq h^{\lambda*} (x) .
\]
Observe that \( h^\alpha \) is intuitively the \( \alpha \)th (transfinite) iterate of the function \( h \). As with the Cichoń hierarchy, one case is of particular interest: that of \( (H^\alpha)_\alpha \) for \( H(x) \triangleq x + 1 \). The Hardy hierarchy will be used in the following exercises and, quite crucially, in Chapter 3.

1. Show that \( H_\alpha(x) = H^\alpha(x) - x \) for all \( \alpha, x \). What about \( h_{\alpha_1}(x) \) and \( h^\alpha(x) - x \) if \( h(x) > x \)?

2. Show that \( h^{\gamma+\alpha}(x) = h^{\gamma}(h^\alpha(x)) \) for all \( h, \gamma, \alpha, x \) with \( \gamma + \alpha \) in CNF.

3. Extend the fast-growing hierarchy to \( (F_\alpha)_\alpha \) by \( F_{\alpha+1}(x) \triangleq F^{\omega x}(x) \) and \( F_\lambda(x) \triangleq F_{\lambda_x}(x) \). Show that \( H^{\omega^\gamma}(x) = F_\alpha(x) \) for all \( \alpha, x \).

4. Show that \( h^{\gamma+\alpha}(x) = h_\gamma( h^\alpha(x) ) + h_\alpha(x) \) for all \( h, \gamma, \alpha, x \) with \( \gamma + \alpha \) in CNF.

5. Show that \( h_{\alpha} \) measures the finite length of the iteration in \( h^\alpha \), i.e. that \( h^\alpha(x) = h^{h_{\alpha}(x)}(x) \) for all \( h, \alpha, x \)—which explains why the Cichoń hierarchy is also called the length hierarchy.

Exercise 2.14 (Finite Values in Coverability Trees). Consider the Karp & Miller coverability tree of a \( d \)-dimensional VAS \( (A, x_0) \) with maximal increment \( b = \max a \in A | a | \), and maximal initial counter value \( n = | x_0 | \). Show using Exercise 2.13 that the finite values in this tree are bounded by \( h^{\omega d - d}(nd) \) for \( h(x) = x + db \).

** Exercise 2.15 (Bad Lexicographic Sequences). We consider in this exercise bad sequences over \( \mathbb{N}^d \) for the lexicographic ordering \( \leq_{\text{lex}} \) (with most significant element last) defined by

\[
\text{x <}_{\text{lex}} \text{y} \iff x(d) < y(d) \text{ or } (x(d) = y(d) \text{ and } (x(1), \ldots, x(d-1)) <_{\text{lex}} (y(1), \ldots, y(d-1))) .
\]

This is a linearization of the product ordering over \( \mathbb{N}^d \); writing \( \mathbb{N}^d_{\text{lex}} \) for the associated nwqo \( (\mathbb{N}^d, \leq_{\text{lex}}, | |) \), we see that

\[
L_g,\mathbb{N}^d_{\text{lex}}(n) \leq L_g,\mathbb{N}^d(n)
\]

for all control functions \( g \) and initial norms \( n \).

Since \( \leq_{\text{lex}} \) is linear, there is a unique maximal \((g, n)\)-controlled bad sequence over \( \mathbb{N}^d_{\text{lex}} \), which will be easy to measure. Our purpose is to prove that for all \( n \),

\[
L_g,\mathbb{N}^d_{\text{lex}}(n) = g_{\omega^d}(n) .
\]

(1) Let \( n > 0 \), and write a program \( \text{LEX}_d(g, n) \) with \( d \) counters \( x(1), \ldots, x(d) \) whose configurations encode the \( d \) coordinates of the maximal \((g, n)\)-controlled bad sequence over \( \mathbb{N}^d_{\text{lex}} \), along with an additional counter \( c \) holding the current value of the control. The run of \( \text{LEX}_d(g, n) \) should be a sequence \((x_1, c_1), (x_2, c_2), \ldots, (x_\ell, c_\ell)\) of pairs \((x_i, c_i)\) composed of a vector \( x_i \) in \( \mathbb{N}^d \) and of a counter \( c_i \).

(2) Let \((x_1, c_1), (x_2, c_2), \ldots, (x_\ell, c_\ell)\) be the unique run of \( \text{LEX}_d(g, n) \) for \( n > 0 \). Define

\[
\alpha(x) = \omega^d - 1 \cdot x(d) + \cdots + \omega^0 \cdot x(1)
\]

for any vector \( x \) in \( \mathbb{N}^d \). Show that, for each \( i > 0 \),

\[
g_{\alpha}(n) = i + g_{\alpha(x_i)}(c_i) .
\]
(3) Deduce (1).

(4) Show that, if \((x_1, c_1), (x_2, c_2), \ldots, (x_\ell, c_\ell)\) is the run of \(\text{lex}_d(g, n)\) for \(n > 0\), then \(c_\ell = g^{\omega d}(n)\).

**Bibliographic Notes**

This chapter is based mostly on (Figueira et al., 2011; Schmitz and Schnoebelen, 2011). The reader will find earlier analyses of Dickson’s Lemma in the works of McAloon (1984) and Clote (1986), who employ large intervals in a sequence and their associated Ramsey theory (Ketonen and Solovay, 1981), showing that large enough intervals would result in good sequences. Different combinatorial arguments are provided by Friedman (2001, Theorem 6.2) for bad sequences over \(\mathbb{N}_d\), and Howell et al. (1986) for sequences of VASS configurations—where even tighter upper bounds are obtained for Exercise 2.14.

Complexity upper bounds have also been obtained for wqos beyond Dickson’s Lemma: Schmitz and Schnoebelen (2011), from which the general framework of normed wqos and derivations is borrowed, tackle Higman’s Lemma and so do Cichoń and Tahhan Bittar (1998) and Weiermann (1994); furthermore the latter provides upper bounds for the more general Tree Theorem of Kruskal.

The hierarchy \((\mathcal{F}_k)_{k \geq 2}\) described as the Grzegorczyk hierarchy in Section 2.1.3 and Section 2.4 is actually due to Löb and Wainer (1970); its relationship with the original Grzegorczyk hierarchy \((\mathcal{E}^k)_k\) (Grzegorczyk, 1953) is that \(\mathcal{F}_k = \mathcal{E}^{k+1}\) for all \(k \geq 2\). There are actually some difference between our definition of \((F_k)_k\) and that of Löb and Wainer (1970), but it only impacts low indices \(k < 2\), and our definition follows contemporary presentations. Maximal order types were defined by de Jongh and Parikh (1977), where the reader will find a proof of Fact 2.23. The CICHÓN hierarchy was first published in (Cichoń and Tahhan Bittar, 1998), where it was called the length hierarchy. More material on subrecursive hierarchies can be found in textbooks (Rose, 1984; Fairtlough and Wainer, 1998; Odifreddi, 1999) and in Appendix A. Fact 2.29 is proven there as Equation (A.25), and Fact 2.30 is a consequence of lemmas A.6, A.9, and A.16.
The previous chapter has established some very high complexity upper bounds on algorithms that rely on Dickson’s Lemma over $d$-tuples of natural numbers for termination. The Length Function Theorem shows that these bounds can be found in every level of the Grzegorczyk hierarchy when $d$ varies, which means that these bounds are Ackermannian when $d$ is part of the input.

Given how large these bounds are, one should wonder whether they are useful at all, i.e. whether there exist natural decision problems that require Ackermannian resources for their resolution. It turns out that such Ackermann complexities pop up regularly with counter systems and Dickson’s Lemma—see Section B.2 for more examples. We consider in this chapter the case of lossy counter machines.

Lossy counter machines and Reset Petri nets are two computational models that can be seen as weakened versions of Minsky counter machines. This weakness explains why some problems (e.g. termination) are decidable for these two models, while they are undecidable for the Turing-powerful Minsky machines.

While these positive results have been used in the literature, there also exists a negative side that has had much more impact. Indeed, decidable verification problems for lossy counter machines are Ackermann-hard and hence cannot be answered in primitive-recursive time or space. The construction can also be adapted to Reset Petri nets, incrementing counter machines, etc.

**Theorem 3.1** (Hardness Theorem). Reachability, termination and coverability for lossy counter machines are Ackermann-hard.

Termination and coverability for Reset Petri nets are Ackermann-hard.

These hardness results turn out to be relevant in several other areas; see the Bibliographic Notes at the end of the chapter.
Chapter 3. Complexity Lower Bounds

Outline. Section 3.1 defines counter machines, both reliable and lossy. Section 3.2 builds counter machines that compute Ackermann’s function. Section 3.3 puts Minsky machines on a budget, a gadget that is essential in Section 3.4 where the main reduction is given and the hardness of reachability and coverability for lossy counter machines is proved. We then show how to deal with reset nets in Section 3.5 and how to prove hardness of termination in Section 3.6.

3.1 Counter Machines

Counter machines are a model of computation where a finite-state control acts upon a finite number of counters, i.e. storage locations that hold a natural number. The computation steps are usually restricted to simple tests and updates. For Minsky machines, the tests are zero-tests and the updates are increments and decrements.

For our purposes, it will be convenient to use a slightly extended model that allows more concise constructions, and that will let us handle reset nets smoothly.

3.1.1 Extended Counter Machines

Formally, an extended counter machine with \( n \) counters, often just called a counter machine (CM), is a tuple \( M = (\text{Loc}, C, \Delta) \) where \( \text{Loc} = \{\ell_1, \ldots, \ell_p\} \) is a finite set of locations, \( C = \{c_1, \ldots, c_n\} \) is a finite set of counters, and \( \Delta \subseteq \text{Loc} \times \text{OP}(C) \times \text{Loc} \) is a finite set of transition rules. The transition rules are depicted as directed edges (see figs. 3.1 to 3.3 below) between control locations labeled with an instruction \( \text{op} \in \text{OP}(C) \) that is either a guard (a condition on the current contents of the counters for the rule to be fireable), or an update (a method that modifies the contents of the counters), or both. For CMs, the instruction set \( \text{OP}(C) \) is given by the following abstract grammar:

\[
\text{OP}(C) \ni \text{op} ::= \begin{array}{l}
c=0? \quad \text{/* zero test */} \quad \text{c:=0} \quad \text{/* reset */} \\
| c>0? \text{c}-- \quad \text{/* decrement */} \quad | \text{c=c’?} \quad \text{/* equality test */} \\
| \text{c}++ \quad \text{/* increment */} \quad | \text{c:=c’} \quad \text{/* copy */}
\end{array}
\]

where \( c, c’ \) are any two counters in \( C \). (We also allow a no_op instruction that does not test or modify the counters.)

A Minsky machine is a CM that only uses instructions among zero tests, decrements and increments (the first three types). Petri nets and Vector Addition Systems with States (VASS) can be seen as counter machines that only use decrements and increments (i.e. Minsky machines without zero-tests).

3.1.2 Operational Semantics

The operational semantics of a CM \( M = (\text{Loc}, C, \Delta) \) is given under the form of transitions between its configurations. Formally, a configuration (written \( \sigma, \theta, \ldots \)
of \( M \) is a tuple \((\ell, a)\) with \( \ell \in \text{Loc} \) representing the “current” control location, and \( a \in \mathbb{N}^C \), a \( C \)-indexed vector of natural numbers representing the current contents of the counters. If \( C \) is some \( \{c_1, \ldots, c_n\} \), we often write \((\ell, a)\) under the form \((\ell, a_1, \ldots, a_n)\). Also, we sometimes use labels in vectors of values to make them more readable, writing e.g. \( a = (0, \ldots, 0, c_k:1, 0, \ldots, 0) \).

Regarding the behavior induced by the rules from \( \Delta \), there is a transition (also called a step) \( \sigma \xrightarrow{\delta} \sigma' \) if, and only if, \( \sigma \) is some \((\ell, a_1, \ldots, a_n)\), \( \sigma' \) is some \((\ell', a'_1, \ldots, a'_n)\), \( \Delta \ni \delta = (\ell, op, \ell') \) and either:

- \( op \) is \( c_k=0? \) (zero test): \( a_k = 0 \), and \( a'_i = a_i \) for all \( i \neq k \), or
- \( op \) is \( c_k>0? c_k-- \) (decrement): \( a'_k = a_k - 1 \), and \( a'_i = a_i \) for all \( i \neq k \), or
- \( op \) is \( c_k++ \) (increment): \( a'_k = a_k + 1 \), and \( a'_i = a_i \) for all \( i \neq k \), or
- \( op \) is \( c_k:=0 \) (reset): \( a'_k = 0 \), and \( a'_i = a_i \) for all \( i \neq k \), or
- \( op \) is \( c_k=c_p? \) (equality test): \( a_k = a_p \), and \( a'_i = a_i \) for all \( i = 1, \ldots, n \), or
- \( op \) is \( c_k:=c_p \) (copy): \( a'_k = a_p \), and \( a'_i = a_i \) for all \( i \neq k \).

(The steps carry a “std” subscript to emphasize that we are considering the usual, standard, operational semantics of counter machines, where the behavior is reliable.)

As usual, we write \( \sigma \xrightarrow{\Delta} \sigma' \), or just \( \sigma \xrightarrow{\text{std}} \sigma' \), when \( \sigma \xrightarrow{\delta} \sigma' \) for some \( \delta \in \Delta \). Chains \( \sigma_0 \xrightarrow{\text{std}} \sigma_1 \xrightarrow{\text{std}} \cdots \xrightarrow{\text{std}} \sigma_m \) of consecutive steps, also called runs, are denoted \( \sigma_0 \xrightarrow{\ast} \sigma_m \), and also \( \sigma_0 \xrightarrow{+} \sigma_m \) when \( m > 0 \). Steps may also be written more precisely under the form \( M \xrightarrow{\delta} \sigma \xrightarrow{\text{std}} \sigma' \) when several counter machines are at hand and we want to be explicit about where the steps take place.

For a vector \( a = (a_1, \ldots, a_n) \), or a configuration \( \sigma = (\ell, a) \), we let \( |a| = |\sigma| = \sum_{i=1}^{n} a_i \) denote its size. For \( N \in \mathbb{N} \), we say that a run \( \sigma_0 \xrightarrow{\text{std}} \sigma_1 \xrightarrow{\text{std}} \cdots \xrightarrow{\text{std}} \sigma_m \) is \( N \)-bounded if \( |\sigma_i| \leq N \) for all \( i = 0, \ldots, n \).

### 3.1.3 Lossy Counter Machines

**Lossy counter machines** (LCM) are counter machines where the contents of the counters can decrease non-deterministically (the machine can “leak”, or “lose data”).

Technically, it is more convenient to see lossy machines as counter machines with a different operational semantics (and not as a special class of machines): thus it is possible to use simultaneously the two semantics and relate them. Incrementing errors too are handled by introducing a different operational semantics, see Exercise 3.3.
Formally, this is defined via the introduction of a partial ordering between the configurations of $M$:

$$(\ell, a_1, \ldots, a_n) \leq (\ell', a'_1, \ldots, a'_n) \iff \ell = \ell' \land a_1 \leq a'_1 \land \cdots \land a_n \leq a'_n. \quad (3.1)$$

$\sigma \leq \sigma'$ can be read as “$\sigma$ is $\sigma'$ after some losses (possibly none).”

Now “lossy” steps, denoted $M \vdash \sigma \xrightarrow{\delta_{\text{lossy}}} \sigma'$, are given by the following definition:

$$\sigma \xrightarrow{\delta_{\text{lossy}}} \sigma' \iff \exists \theta, \theta', (\sigma \geq \theta \land \theta \xrightarrow{\delta_{\text{std}}} \theta' \land \theta' \geq \sigma'). \quad (3.2)$$

Note that reliable steps are a special case of lossy steps:

$$M \vdash \sigma \xrightarrow{\text{std}} \sigma' \text{ implies } M \vdash \sigma \xrightarrow{\text{lossy}} \sigma'. \quad (3.3)$$

### 3.1.4 Behavioral Problems on Counter Machines

We consider the following decision problems:

**Reachability:** given a CM $M$ and two configurations $\sigma_{\text{ini}}$ and $\sigma_{\text{goal}}$, is there a run $M \vdash \sigma_{\text{ini}} \xrightarrow{*} \sigma_{\text{goal}}$?

**Coverability:** given a CM $M$ and two configurations $\sigma_{\text{ini}}$ and $\sigma_{\text{goal}}$, is there a run $M \vdash \sigma_{\text{ini}} \xrightarrow{*} \sigma$ for some configuration $\sigma \geq \sigma_{\text{goal}}$ that covers $\sigma_{\text{goal}}$?

**(Non-)Termination:** given a CM $M$ and a configuration $\sigma_{\text{ini}}$, is there an infinite run $M \vdash \sigma_{\text{ini}} \xrightarrow{\sigma_1 \rightarrow \cdots \rightarrow \sigma_n \rightarrow \cdots}$?

These problems are parameterized by the class of counter machines we consider and, more importantly, by the operational semantics that is assumed. Reachability and termination are decidable for lossy counter machines, i.e. counter machines assuming lossy steps, because they are well-structured. Observe that, for lossy machines, reachability and coverability coincide (except for runs of length 0). Coverability is often used to check whether a control location is reachable from some $\sigma_{\text{ini}}$. For the standard semantics, the same problems are undecidable for Minsky machines but become decidable for VASS and, except for reachability, for Reset nets (see Section 3.5).

### 3.2 Hardy Computations

The Hardy hierarchy $(H^\alpha : \mathbb{N} \to \mathbb{N})_{\alpha < \varepsilon_0}$ is a hierarchy of ordinal-indexed functions, much like the Cichoń hierarchy introduced in Section 2.4.2. Its definition and properties are the object of Exercise 2.13 on page 49, but let us recall the following:

$$H^0(n) \overset{\text{def}}{=} n, \quad H^{\alpha+1}(n) \overset{\text{def}}{=} H^\alpha(n + 1), \quad H^\lambda(n) \overset{\text{def}}{=} H^{\lambda n}(n). \quad (3.4)$$
Observe that $H^1$ is the successor function, and more generally $H^\alpha$ is the $\alpha$th iterate of the successor function, using diagonalisation to treat limit ordinals. Its relation with the fast growing hierarchy $(F_\alpha)_{\alpha < \varepsilon_0}$ is that

$$H^{\omega \alpha}(n) = F_\alpha(n) \tag{3.5}$$

while its relation with the Cichoń hierarchy $(H_\alpha)_{\alpha < \varepsilon_0}$ is that

$$H^\alpha(n) = H_\alpha(n) + n \tag{3.6}.$$  

Thus $H^\omega(n) = H^n(n) = 2n + 1$, $H^\omega^2(n) = 2^{n+1}(n+1) - 1$ is exponential, $H^\omega^3$ non-elementary, and $H^\omega^\omega$ Ackermannian; in fact we set in this chapter

$$\text{Ack}(n) \overset{\text{def}}{=} F_\omega(n) = H^{\omega \omega}(n) = H^{\omega^n}(n). \tag{3.7}$$

Two facts that we will need later can be deduced from (3.6) and the corresponding properties for the functions in the Cichoń hierarchy: Hardy functions are monotone in their argument:

**Fact 3.2** (see Fact 2.29). If $n \leq n'$ then $H^\alpha(n) \leq H^\alpha(n')$ for all $\alpha < \varepsilon_0$.

They are also monotone in their parameter relatively to the structural ordering defined in Section 2.4.3 on page 44:

**Fact 3.3** (see Exercise 2.11). If $\alpha \subseteq \alpha'$, then $H^\alpha(n) \leq H^{\alpha'}(n)$ for all $n$.

The $(F_\alpha)_{\alpha}$ hierarchy provides a more abstract packaging of the main stops of the (extended) Grzegorczyk hierarchy and requires lighter notation than the Hardy hierarchy $(H^\alpha)_{\alpha}$. However, with its tail-recursive definition, the Hardy hierarchy is easier to implement as a while-program or as a counter machine. Below we weakly implement Hardy computations with CMs. Formally, a (forward) Hardy computation is a sequence

$$\alpha_0; n_0 \rightarrow \alpha_1; n_1 \rightarrow \alpha_2; n_2 \rightarrow \cdots \rightarrow \alpha_\ell; n_\ell \tag{3.8}$$

of evaluation steps implementing the equations in (3.4) seen as left-to-right rewrite rules. It guarantees $\alpha_0 > \alpha_1 > \alpha_2 > \cdots$ and $n_0 \leq n_1 \leq n_2 \leq \cdots$ and keeps $H^{\alpha_i}(n_i)$ invariant. We say it is complete when $\alpha_\ell = 0$ and then $n_\ell = H^{\alpha_0}(n_0)$ (we also consider incomplete computations). A backward Hardy computation is obtained by using (3.4) as right-to-left rules. For instance,

$$\omega^\omega; m \rightarrow \omega^m; m \rightarrow \omega^{m-1} \cdot m; m \tag{3.9}$$

constitute the first three steps of the forward Hardy computation starting from $\omega^\omega; m$ if $m > 0$.  

Hardy computation
3.2.1 Encoding Hardy Computations

Ordinals below $\omega^{m+1}$ are easily encoded as vectors in $\mathbb{N}^{m+1}$: given a vector $a = (a_m, \ldots, a_0) \in \mathbb{N}^{m+1}$, we define its associated ordinal in $\omega^{m+1}$ as

$$\alpha(a) \equiv \omega^m \cdot a_m + \omega^{m-1} \cdot a_{m-1} + \cdots + \omega^0 \cdot a_0.$$  \hspace{1cm} (3.10)

Observe that ordinals below $\omega^{m+1}$ and vectors in $\mathbb{N}^{m+1}$ are in bijection through $\alpha$.

We can then express Hardy computations for ordinals below $\omega^{m+1}$ as a rewrite system $\Rightarrow^H$ over pairs $\langle a; n \rangle$ of vectors in $\mathbb{N}^{m+1}$ and natural numbers:

$$\langle a_m, \ldots, a_0 + 1; n \rangle \rightarrow \langle a_m, \ldots, a_0; n + 1 \rangle,$$  \hspace{1cm} (D1)

$$\langle a_m, \ldots, a_k + 1, 0, \ldots, 0; n \rangle \rightarrow \langle a_m, \ldots, a_k, n + 1, 0, \ldots, 0; n \rangle.$$  \hspace{1cm} (D2)

The two rules (D1) and (D2) correspond to the successor and limit case of (3.4), respectively. Computations with these rules keep $H^\alpha(a)(n)$ invariant.

A key property of this encoding is that it is robust in presence of “losses.” Indeed, if $a \leq a'$, then $\alpha(a) \equiv \alpha(a')$ and Fact 3.3 shows that $H^\alpha(a)(n) \leq H^\alpha(a')(n)$. More generally, adding Fact 3.3 to the mix,

**Lemma 3.4 (Robustness).** If $a \leq a'$ and $n \leq n'$ then $H^\alpha(a)(n) \leq H^\alpha(a')(n')$.

Now, $H^\rightarrow$ terminates since $\langle a; n \rangle \rightarrow^H \langle a'; n' \rangle$ implies $\alpha(a) > \alpha(a')$. Furthermore, if $a \neq 0$, one of the rules among (D1) and (D2) can be applied to $\langle a; n \rangle$. Hence for all $a$ and $n$ there exists some $n'$ such that $\langle a; n \rangle \rightarrow^H \star \langle 0; n' \rangle$, and then $n' = H^\alpha(a)(n)$. The reverse relation $\rightarrow^{-1}$ terminates as well since, in a step $\langle a'; n' \rangle \rightarrow^H \star \langle a; n \rangle$, either $n'$ is decreased, or it stays constant and the number of zeroes in $a'$ is increased.

3.2.2 Implementing Hardy Computations with Counter Machines

Being tail-recursive, Hardy computations can be evaluated via a simple while-loop that implements the $H^\rightarrow$ rewriting. Fix a level $m \in \mathbb{N}$: we need $m + 2$ counters, one for the $n$ argument, and $m + 1$ for the $a \in \mathbb{N}^{m+1}$ argument.

We define a counter machine $M_H(m) = (\text{Loc}_H, C, \Delta_H)$, or $M_H$ for short, with $C = \{ a_0, a_1, \ldots, a_m, n \}$. Its rules are defined pictorially in Figure 3.1: they implement $H^\rightarrow$ as a loop around a central location $\ell_H$, as captured by the following lemma, which relies crucially on Lemma 3.4:

**Lemma 3.5 (Behavior of $M_H$).** For all $a, a' \in \mathbb{N}^{m+1}$ and $n, n' \in \mathbb{N}$:

1. If $\langle a; n \rangle \rightarrow^H \langle a'; n' \rangle$ then $M_H \downarrow (\ell_H, a, n) \rightarrow^*_{\text{std}} (\ell_H, a', n')$.  

2. If $M_H \vdash (\ell_H, a, n) \rightarrow_{std}^* (\ell_H, a', n')$ then $H^\alpha(a)(n) = H^\alpha(a')(n')$.

3. If $M_H \vdash (\ell_H, a, n) \rightarrow_{lossy}^* (\ell_H, a', n')$ then $H^\alpha(a)(n) \geq H^\alpha(a')(n')$.

The rules (D1–D2) can also be used from right to left. Used this way, they implement backward Hardy computations, i.e. they invert $H$. This is implemented by another counter machine, $M_{H^{-1}}(m) = (\text{Loc}_{H^{-1}}, C, \Delta_{H^{-1}})$, or $M_{H^{-1}}$ for short, defined pictorially in Figure 3.2.

$M_{H^{-1}}$ implements $H^{-1}$ as a loop around a central location $\ell_{H^{-1}}$, as captured by Lemma 3.6. Note that $M_{H^{-1}}$ may deadlock if it makes the wrong guess as whether $a_i$ contains $n + 1$, but this is not a problem with the construction.

**Lemma 3.6 (Behavior of $M_{H^{-1}}$).** For all $a, a' \in \mathbb{N}^{m+1}$ and $n, n' \in \mathbb{N}$:

1. If $(a; n) \xrightarrow{H} (a'; n')$ then $M_{H^{-1}} \vdash (\ell_{H^{-1}}, a', n') \rightarrow_{std}^* (\ell_{H^{-1}}, a, n)$.

2. If $M_{H^{-1}} \vdash (\ell_{H^{-1}}, a, n) \rightarrow_{std}^* (\ell_{H^{-1}}, a', n')$ then $H^\alpha(a)(n) = H^\alpha(a')(n')$.

3. If $M_{H^{-1}} \vdash (\ell_{H^{-1}}, a, n) \rightarrow_{lossy}^* (\ell_{H^{-1}}, a', n')$ then $H^\alpha(a)(n) \geq H^\alpha(a')(n')$.

### 3.3 Minsky Machines on a Budget

With a Minsky machine $M = (\text{Loc}, C, \Delta)$ we associate a Minsky machine $M^b = (\text{Loc}_b, C_b, \Delta_b)$. (Note that we are only considering Minsky machines here, and not the extended counter machines from earlier sections.)

$M^b$ is obtained by adding to $M$ an extra “budget” counter $B$ and by adapting the rules of $\Delta$ so that any increment (resp. decrement) in the original counters is balanced by a corresponding decrement (resp. increment) on the new counter $B$, along with appropriate new states. The rules are as follows:

1. For all $\ell, a, n \in \text{Loc} \times \mathbb{N}$
   
   - If $\ell = \ell_{\text{init}}$ and $a_0 > 0$, then $a_0 := n + 1$.
   
   - If $\ell = \ell_{\text{end}}$ and $a_m = 0$, then $a_m := n + 1$.

2. For all $\ell, a, n \in \text{Loc} \times \mathbb{N}$
   
   - If $\ell = \ell_1$ and $a_1 = 0$, then $a_1 := n + 1$.
   
   - If $\ell = \ell_2$ and $a_2 = 0$, then $a_2 := n + 1$.
   
   - For $i = 1, 2, \ldots, m$
     
     - If $\ell = \ell_i$ and $a_i = 0$, then $a_i := n + 1$.

3. For all $\ell, a, n \in \text{Loc} \times \mathbb{N}$
   
   - If $\ell = \ell_1$ and $a_1 > 0$, then $a_1 := a_1 - 1$.
   
   - If $\ell = \ell_2$ and $a_2 > 0$, then $a_2 := a_2 - 1$.
   
   - For $i = 1, 2, \ldots, m$
     
     - If $\ell = \ell_i$ and $a_i > 0$, then $a_i := a_i - 1$.

4. For all $\ell, a, n \in \text{Loc} \times \mathbb{N}$
   
   - If $\ell = \ell_{\text{init}}$ and $a_0 < 0$, then $a_0 := a_0 + 1$.
   
   - If $\ell = \ell_{\text{end}}$ and $a_m < 0$, then $a_m := a_m + 1$.

5. For all $\ell, a, n \in \text{Loc} \times \mathbb{N}$
   
   - If $\ell = \ell_1$ and $a_1 < 0$, then $a_1 := a_1 + 1$.
   
   - If $\ell = \ell_2$ and $a_2 < 0$, then $a_2 := a_2 + 1$.
   
   - For $i = 1, 2, \ldots, m$
     
     - If $\ell = \ell_i$ and $a_i < 0$, then $a_i := a_i + 1$.

By these rules, the budget counter $B$ is decremented or incremented as necessary to balance the changes in the original counters.
Figure 3.2: $M_{H^{-1}}(m)$, a counter machine that implements $H^{-1}$.

Figure 3.3: From $M$ to $M^b$ (schematically).

so that the sum of the counters remains constant. This is a classic idea in Petri nets. The construction is described on a schematic example (Figure 3.3) that is clearer than a formal definition. Observe that extra intermediary locations (in gray) are used, and that a rule in $M$ that increments some $c_i$ will be forbidden in $M^b$ when the budget is exhausted.

We now collect the properties of this construction that will be used later. The fact that $M^b$ faithfully simulates $M$ is stated in lemmas 3.8 and 3.9. There and at other places, the restriction to “$\ell, \ell' \in \text{Loc}$” ensures that we only relate behavior anchored at the original locations in $M$ (locations that also exist in $M^b$) and not at one of the new intermediary locations introduced in $M^b$.

First, the sum of the counters in $M^b$ is a numerical invariant (that is only temporarily disrupted while in the new intermediary locations).

**Lemma 3.7.** If $M^b \vdash (\ell, B, a) \rightarrow^*_{\text{std}} (\ell', B', a')$ and $\ell, \ell' \in \text{Loc}$, then $B + |a| = B' + |a'|$. 

Observe that $M^b$ can only do what $M$ would do:

**Lemma 3.8.** If $M^b \vdash (\ell, B, a) \rightarrow^{\text{std}}_{\text{loc}} (\ell', B', a')$ and $\ell, \ell' \in \text{Loc}$ then $M \vdash (\ell, a) \rightarrow^{\text{std}}_{\text{loc}} (\ell', a')$.

Reciprocally, everything done by $M$ can be mirrored by $M^b$ provided that a large enough budget is allowed. More precisely:

**Lemma 3.9.** If $M \vdash (\ell, a) \rightarrow^{\text{std}}_{\text{loc}} (\ell', a')$ is an $N$-bounded run of $M$, then $M^b$ has an $N$-bounded run $M^b \vdash (\ell, B, a) \rightarrow^{\text{loc}}_{\text{std}} (\ell', B', a')$ for $B \overset{\text{def}}{=} N - |a|$ and $B' \overset{\text{def}}{=} N - |a'|$.

Now, the point of the construction is that $M^b$ can distinguish between lossy and non-lossy runs in ways that $M$ cannot. More precisely:

**Lemma 3.10.** Let $M^b \vdash (\ell, B, a) \rightarrow^{\text{loc}}_{\text{loc}} (\ell', B', a')$ with $\ell, \ell' \in \text{Loc}$. Then $M^b \vdash (\ell, B, a) \rightarrow^{\text{std}}_{\text{std}} (\ell', B', a')$ if, and only if, $B + |a| = B' + |a'|$.

**Proof Idea.** The ‘‘($\iff$)’’ direction is an immediate consequence of (3.3).

For the ‘‘($\Rightarrow$)’’ direction, we consider the hypothesized run $M^b \vdash (\ell, B, a) = \sigma_0 \rightarrow_{\text{loc}} \sigma_1 \rightarrow_{\text{loc}} \cdots \rightarrow_{\text{loc}} \sigma_n = (\ell', B', a')$. Coming back to (3.2), these lossy steps require, for $i = 1, \ldots, n$, some reliable steps $\theta_{i-1} \rightarrow^{\text{std}}_{\text{std}} \theta_i$ with $\sigma_i \geq \theta_{i-1}$ and $\theta_i \geq \sigma_i$, and hence $|\theta'_i| \geq |\theta_i|$ for $i < n$. Combining with $|\theta_{i-1}| = |\theta'_i|$ (by Lemma 3.7), and $|\sigma_0| = |\sigma_n|$ (from the assumption that $B + |a| = B' + |a'|$), proves that all these configurations have same size. Hence $\theta'_i = \sigma_i = \theta_i$ and the lossy steps are also reliable steps.

**Corollary 3.11.** Assume $M^b \vdash (\ell, B, 0) \rightarrow^{\text{loc}}_{\text{loc}} (\ell', B', a)$ with $\ell, \ell' \in \text{Loc}$. Then:

1. $B \geq B' + |a|$, and

2. $M \vdash (\ell, 0) \rightarrow^{\text{std}}_{\text{std}} (\ell', a)$ if, and only if, $B = B' + |a|$. Furthermore, this reliable run of $M$ is $B$-bounded.

### 3.4 Ackermann-Hardness for Lossy Counter Machines

We now collect the ingredients that have been developed in the previous sections.

Let $M$ be a Minsky machine with two fixed “initial” and “final” locations $\ell_{\text{ini}}$ and $\ell_{\text{fin}}$. With $M$ and a level $m \in \mathbb{N}$ we associate a counter machine $M(m)$ obtained by stringing together $M_{H}(m)$, $M^b$, and $M_{H-1}(m)$ and fusing the extra budget counter $B$ from $M^b$ with the accumulator $n$ of $M_{H}(m)$ and $M_{H-1}(m)$ (these two share their counters). The construction is depicted in Figure 3.4.

**Proposition 3.12.** The following are equivalent:

1. $M(m)$ has a lossy run $(\ell_{H}, a_m:1, 0, n:m, 0) \rightarrow^{\text{loc}}_{\text{loc}} \theta$ for some $\theta$ no smaller than $(\ell_{H-1}, 1, 0, m, 0)$. 

2. \( M^b \) has a lossy run \((\ell_{\text{ini}}; B; \text{Ack}(m), 0) \rightarrow^*_{\text{lossy}} (\ell_{\text{fin}}, \text{Ack}(m), 0)\).

3. \( M^b \) has a reliable run \((\ell_{\text{ini}}, \text{Ack}(m), 0) \rightarrow^*_{\text{std}} (\ell_{\text{fin}}, \text{Ack}(m), 0)\).

4. \( M(m) \) has a reliable run \((\ell_H, 1, 0, m, 0) \rightarrow^*_{\text{std}} (\ell_{H-1}, 1, 0, m, 0)\).

5. \( M \) has a reliable run \((\ell_{\text{ini}}, 0) \rightarrow^*_{\text{std}} (\ell_{\text{fin}}, 0) \) that is \( \text{Ack}(m) \)-bounded.

**Proof Sketch.**

- For “1 \( \Rightarrow \) 2,” and because coverability implies reachability by (3.2), we may assume that \( M(m) \) has a run \((\ell_H, 1, 0, m, 0) \rightarrow^*_{\text{lossy}} (\ell_{H-1}, 1, 0, m, 0)\). This run must go through \( M^b \) and be in three parts of the following form:

  \[
  (\ell_H, 1, 0, m, 0) \xrightarrow{\Delta_H^*} (\ell_H, a, n:x, 0) \quad \text{(starts in } M_H) \\
  \rightarrow_{\text{lossy}} (\ell_{\text{ini}}\ldots, B, 0) \xrightarrow{\Delta_{H-1}^*} (\ell_{\text{fin}}\ldots, B', c) \quad \text{(goes through } M_b) \\
  \rightarrow_{\text{lossy}} (\ell_{H-1}, a', x', \ldots) \xrightarrow{\Delta_{H-1}^*} (\ell_{H-1}, 1, 0, m, 0). \quad \text{(ends in } M_{H-1})
  \]

  The first part yields \( H^{\alpha(1,0)}(m) \geq H^{\alpha(a)}(x) \) (by **Lemma 3.5**), the third part \( H^{\alpha(a')}(x') \geq H^{\alpha(1,0)}(m) \) (by **Lemma 3.6**), and the middle part \( B \geq B' + |c| \) (by **Corollary 3.11**). Lossiness further implies \( x \geq B, B' \geq x' \) and \( a \geq a' \). Now, the only way to reconcile \( H^{\alpha(a)}(x) \leq H^{\alpha(1,0)}(m) = \text{Ack}(m) \leq H^{\alpha(a')}(x') \), \( a' \leq a, x' \leq x \), and the monotonicity of \( F \) (**Lemma 3.4**) is by concluding \( x = B = B' = x' = \text{Ack}(m) \) and \( c = 0 \). Then the middle part of the run witnesses \( M^b \vdash (\ell_{\text{ini}}, \text{Ack}(m), 0) \rightarrow^*_{\text{lossy}} (\ell_{\text{fin}}, \text{Ack}(m), 0)\).

- “2 \( \Rightarrow \) 5” is **Corollary 3.11**.

- “5 \( \Rightarrow \) 3” is given by **Lemma 3.9**.

- “3 \( \Rightarrow \) 4” is obtained by stringing together reliable runs of the components, relying on lemmas **3.5** and **3.6** for the reliable runs of \( M_H \) and \( M_{H-1} \).
3.5 Handling Reset Petri Nets

Finally “3 ⇒ 2” and “4 ⇒ 1” are immediate from (3.3).

With Proposition 3.12, we have a proof of the Hardness Theorem for reachability and coverability in lossy counter machines: Recall that, for a Minsky machine $M$, the existence of a run between two given configurations is undecidable, and the existence of a run bounded by $\text{Ack}(m)$ is decidable but not primitive-recursive when $m$ is part of the input. Therefore, Proposition 3.12 and in particular the equivalence between its points 1 and 5, states that our construction reduces a nonprimitive-recursive problem to the reachability problem for lossy counter machines.

3.5 Handling Reset Petri Nets

Reset nets are Petri nets extended with special reset arcs that empty a place when a transition is fired. They can equally be seen as special counter machines, called reset machines, where actions are restricted to decrements, increments, and resets—note that zero-tests are not allowed in reset machines.

It is known that termination and coverability are decidable for reset machines while other properties like reachability of a given configuration, finiteness of the reachability set, or recurrent reachability, are undecidable.

Our purpose is to prove the Ackermann-hardness of termination and coverability for reset machines. We start with coverability and refer to Section 3.6 for termination.

3.5.1 Replacing Zero-Tests with Resets

For a counter machine $M$, we let $R(M)$ be the counter machine obtained by replacing every zero-test instruction $c=0?$ with a corresponding reset $c:=0$. Note that $R(M)$ is a reset machine when $M$ is a Minsky machine.

Clearly, the behavior of $M$ and $R(M)$ are related in the following way:

**Lemma 3.13.**

1. $M \vdash \sigma \rightarrow_{\text{std}} \sigma'$ implies $R(M) \vdash \sigma \rightarrow_{\text{std}} \sigma'$.
2. $R(M) \vdash \sigma \rightarrow_{\text{std}} \sigma'$ implies $M \vdash \sigma \rightarrow_{\text{lossy}} \sigma'$.

In other words, the reliable behavior of $R(M)$ contains the reliable behavior of $M$ and is contained in the lossy behavior of $M$.

We now consider the counter machine $M(m)$ defined in Section 3.4 and build $R(M(m))$.

**Proposition 3.14.** The following are equivalent:

1. $R(M(m))$ has a reliable run $(\ell_H, a_m; 1, 0, n;m, 0) \rightarrow_{\text{std}}^s (\ell_{H-1}, 1, 0, m, 0)$.
2. $R(M(m))$ has a reliable run $(\ell_H, 1, 0, m, 0) \to^*_\text{std} \theta \geq (\ell_{H^{-1}}, 1, 0, m, 0)$.

3. $M$ has a reliable run $(\ell_{\text{ini}}, 0) \to^*_\text{std} (\ell_{\text{fin}}, 0)$ that is $\text{Ack}(m)$-bounded.

Proof. For $1 \Rightarrow 3$: The reliable run in $R(M(m))$ gives a lossy run in $M(m)$ (Lemma 3.13[2]), and we conclude using “1$\Rightarrow$5” in Proposition 3.12.

For $3 \Rightarrow 2$: We obtain a reliable run in $M(m)$ (“5$\Rightarrow$4” in Proposition 3.12) which gives a reliable run in $R(M(m))$ (Lemma 3.13[1]), which in particular witnesses coverability.

For $2 \Rightarrow 1$: The covering run in $R(M(m))$ gives a lossy covering run in $M(m)$ (Lemma 3.13[2]), hence also a lossy run in $M(m)$ that reaches exactly $(\ell_{H^{-1}}, 1, 0, m, 0)$ (e.g. by losing whatever is required at the last step). From there we obtain a reliable run in $M(m)$ (“1$\Rightarrow$4” in Proposition 3.12) and then a reliable run in $R(M(m))$ (Lemma 3.13[1]).

We have thus reduced an Ackermann-hard problem (point 3 above) to a coverability question (point 2 above).

This almost proves the Hardness Theorem for coverability in reset machines, except for one small ingredient: $R(M(m))$ is not a reset machine properly because $M(m)$ is an extended counter machine, not a Minsky machine. I.e., we proved hardness for “extended” reset machines. Before tackling this issue, we want to point out that something as easy as the proof of Proposition 3.14 will prove Ackermann-hardness of reset machines by reusing the hardness of lossy counter machines.

In order to conclude the proof of the Hardness Theorem for reset machines, we only need to provide versions of $M_H$ and $M_{H^{-1}}$ in the form of Minsky machines ($M$ and $M^b$ already are Minsky machines) and plug these in Figure 3.4 and Proposition 3.12.

3.5.2 From Extended to Minsky Machines

There are two reasons why we did not provide $M_H$ and $M_{H^{-1}}$ directly under the form of Minsky machines in Section 3.2. Firstly, this would have made the construction cumbersome: Figure 3.2 is already bordering on the inelegant. Secondly, and more importantly, this would have made the proof of lemmas 3.5 and 3.6 more painful than necessary.

Rather than designing new versions of $M_H$ and $M_{H^{-1}}$, we rely on a generic way of transforming extended counter machines into Minsky machines that preserves both the reliable behavior and the lossy behavior in a sense that is compatible with the proof of Proposition 3.12.

Formally, we associate with any extended counter machine $M = (\text{Loc}, C, \Delta)$ a new machine $M' = (\text{Loc}', C', \Delta')$ such that:

1. $\text{Loc}'$ is $\text{Loc}$ plus some extra “auxiliary” locations,
2. $C' = C + \{\text{aux}\}$ is $C$ extended with one extra counter,

3. $M'$ only uses zero-tests, increments and decrements, hence it is a Minsky machine,

4. For any $\ell, \ell' \in \text{Loc}$ and vectors $c, c' \in \mathbb{N}^C$, the following holds:

$$M \vdash (\ell, c) \xrightarrow{\ast_{\text{std}}} (\ell', c') \iff M' \vdash (\ell, c, 0) \xrightarrow{\ast_{\text{std}}} (\ell', c', 0), \quad (3.11)$$

$$M \vdash (\ell, c) \xrightarrow{\ast_{\text{lossy}}} (\ell', c') \iff M' \vdash (\ell, c, 0) \xrightarrow{\ast_{\text{lossy}}} (\ell', c', 0). \quad (3.12)$$

The construction of $M'$ from $M$ contains no surprise. We replace equality tests, resets and copies by gadgets simulating them and only using the restricted instruction set of Minsky machines. One auxiliary counter aux is used for temporary storage, and several additional locations are introduced each time one extended instruction is replaced.

We show here how to eliminate equality tests and leave the elimination of resets and copies as 

Exercise 3.1 Figure 3.5 shows, on a schematic example, how the transformation is defined.

It is clear (and completely classic) that this transformation satisfies (3.11). The trickier half is the “$\Leftarrow$” direction. Its proof is done with the help of the following observations:

- $c - c'$ is a numerical invariant in $l$, and also in $l'$,
- $c + \text{aux}$ is a numerical invariant in $l$, and also in $l'$,
- when $M'$ moves from $\ell_0$ to $l$, aux contains 0; when it moves from $l$ to $l'$, both $c$ and $c'$ contain 0; when it moves from $l'$ to $\ell_1$, aux contains 0.
Then we also need the less standard notion of correctness from (3.12) for this transformation. The “≤” direction is proved with the help of the following observations:

- \( c - c' \) can only decrease during successive visits of \( l \), and also of \( l' \),
- \( c + \text{aux} \) can only decrease during successive visits of \( l \), and also of \( l' \),
- when \( M' \) moves from \( \ell_0 \) to \( l \), \( \text{aux} \) contains 0; when it moves from \( l \) to \( l' \), both \( c \) and \( c' \) contain 0; when it moves from \( l' \) to \( \ell_1 \), \( \text{aux} \) contains 0.

Gathering these observations, we can conclude that a run \( M' \vdash (\ell_0, c, c', 0) \rightarrow_{\text{lossy}}^* (\ell_1, d, d', 0) \) implies \( d, d' \leq \min(c, c') \). In such a case, \( M \) obviously has a lossy step \( M \vdash (\ell_0, c, c') \rightarrow_{\text{lossy}} (\ell_1, d, d') \).

### 3.6 Hardness for Termination

We can prove hardness for termination by a minor adaptation of the proof for coverability. This adaptation, sketched in Figure 3.6, applies to both lossy counter machines and reset machines.

Basically, \( M^b \) now uses two copies of the initial budget. One copy in \( B \) works as before: its purpose is to ensure that losses will be detected by a budget imbalance as in Lemma 3.10. The other copy, in a new counter \( T \), is a time limit that is initialized with \( n \) and is decremented with every simulated step of \( M \): its purpose is to ensure that the new \( M^b \) always terminates. Since \( M_H \) and \( M_{H-1} \) cannot run forever (because \( H \) and \( H^{-1} \) terminate, see Section 3.2), we now have a new \( M(m) \) that always terminate when started in \( \ell_H \) and that satisfies the following variant of propositions 3.12 and 3.14.

**Proposition 3.15.** The following are equivalent:
Exercises 67

1. \( M(m) \) has a lossy run \( (\ell_H, 1, 0, n:m, 0) \rightarrow_{\text{lossy}}^* \theta \geq (\ell_{H^{-1}}, 1, 0, m, 0) \).

2. \( R(M(m)) \) has a lossy run \( (\ell_H, 1, 0, n:m, 0) \rightarrow_{\text{lossy}}^* \theta \geq (\ell_{H^{-1}}, 1, 0, m, 0) \).

3. \( M \) has a reliable run \( (\ell_{\text{ini}}, 0) \rightarrow_{\text{std}}^* (\ell_{\text{fin}}, 0) \) of length at most \( \text{Ack}(m) \).

Finally, we add a series of \( m + 1 \) transitions that leave from \( \ell_{H^{-1}} \), and check that \( \sigma_{\text{goal}} \overset{m}{\rightarrow} (\ell_{H^{-1}}, 1, 0, m, 0) \) is covered, i.e., that \( a_m \) contains at least 1 and \( n \) at least \( m \). If this succeeds, one reaches a new location \( \ell_{\omega} \), the only place where infinite looping is allowed unconditionally. This yields a machine \( M(m) \) that has an infinite lossy run if, and only if, it can reach a configuration that covers \( \sigma_{\text{goal}} \), i.e., if, and only if, \( M \) has a reliable run of length at most \( \text{Ack}(m) \), which is an Ackermann-hard problem.

**Exercises**

**Exercise 3.1** (From Extended to Minsky Machines). Complete the translation from extended counter machines to Minsky machines given in Section 3.5.2. Provide gadgets for equality tests and resets.

**Exercise 3.2** (Transfer Machines). Transfer machines are extended counter machines with instruction set reduced to increments, decrements, and transfers

\[ c_1 \leftarrow c_2; c_2 : = 0. \quad /\text{ transfer } c_2 \text{ to } c_1 \quad /\]

Show that transfer machines can simulate reset machines as far as coverability and termination are concerned. Deduce that the Hardness Theorem also applies to transfer machines.

**Exercise 3.3** (Incrementing Counter Machines). Incrementing counter machines are Minsky machines with incrementation errors: rather than leaking, the counters may increase nondeterministically, by arbitrary large amounts. This is captured by introducing a new operations semantics for counter machines, with steps denoted \( M \vdash \sigma \rightarrow_{\text{inc}} \sigma' \), and defined by:

\[ \sigma \overset{\delta_{\text{inc}}}{\rightarrow} \sigma', \quad \exists \theta, \theta', (\sigma \leq \theta \land \theta \overset{\delta_{\text{std}}}{\rightarrow} \theta' \land \theta' \leq \sigma'). \quad (\ast) \]

Incrementation errors are thus the symmetrical mirror of losses.

Show that, for a Minsky machine \( M \), one can construct another Minsky machine \( M^{-1} \) with

\[ M \vdash \sigma_1 \rightarrow_{\text{std}} \sigma_2 \iff M^{-1} \vdash \sigma_2 \rightarrow_{\text{std}} \sigma_1. \quad (\dagger) \]

What does it entail for lossy runs of \( M \) and incrementing runs of \( M^{-1} \)? Conclude that reachability for incrementing counter machines is Ackermannian.
This chapter is a slight revision of (Schnoebelen, 2010a), with some changes to use Hardy computations instead of fast-growing ones. Previous proofs of Ackermann-hardness for lossy counter machines or related models were published independently by Urquhart (1999) and Schnoebelen (2002).

We refer the reader to (Mayr, 2000; Schnoebelen, 2010b) for decidability issues for lossy counter machines. Reset nets (Araki and Kasami, 1976; Ciardo, 1994) are Petri nets extended with reset arcs that empty a place when the relevant transition is fired. Transfer nets (Ciardo, 1994) are instead extended with transfer arcs that move all the tokens from a place to another upon transition firing. Decidability issues for Transfer nets and Reset nets are investigated by Dufourd et al. (1999); interestingly, some problems are harder for Reset nets than for Transfer nets, although there exists an easy reduction from one to the others as far as the Hardness Theorem is concerned (see Exercise 3.2).

Using lossy counter machines, hardness results relying on the first half of the Hardness Theorem have been derived for a variety of logics and automata dealing with data words or data trees (Demri, 2006; Demri and Lazic, 2009; Jurdziński and Lazic, 2007; Figueira and Segoufin, 2009; Tan, 2010). Actually, these used reductions from counter machines with incrementation errors (see Exercise 3.3); although reachability for incrementing counter machines is Ackermann-hard, this does not hold for termination (Bouyer et al., 2012).

Ackermann-hardness has also been shown by reductions from Reset and Transfer nets, relying on the second half of the Hardness Theorem (e.g. Amadio and Meyssonnier, 2002; Bresolin et al., 2012).

The techniques presented in this chapter have been extended to considerably higher complexities for lossy channel systems (Chambart and Schnoebelen, 2008b) and enriched nets (Haddad et al., 2012).
Although the interested reader can easily find comprehensive accounts on subrecursive hierarchies (Rose, 1984; Fairtlough and Wainer, 1998; Odifreddi, 1999), we found it convenient to gather in this self-contained appendix many simple proofs and technical results, many too trivial to warrant being published in full, but still useful in the day-to-day work with hierarchies. We also include some results of Cichon and Wainer (1983) and Cichon and Tahhan Bittar (1998), which are harder to find in the literature, and the definition of lean ordinal terms.

The main thrust behind subrecursive functions is to obtain hierarchies of computable functions that lie strictly within the class of all recursive functions. An instance is the extended Grzegorczyk hierarchy \((\mathcal{F}_\alpha)\). Such hierarchies are typically defined by generator functions and closure operators (e.g. primitive recursion, and more generally ordinal recursion), and used to draw connections with proof theory, computability, speed of growth, etc.

Our interest however lies mostly in the properties of particular functions in this theory, like the fast-growing functions \((F_\alpha)\) or the Hardy functions \((H^\alpha)\), which we use as tools for the study of the length of bad sequences.

**A.1 Ordinal Terms**

The reader is certainly familiar with the notion of Cantor normal form (CNF) for ordinals below \(\varepsilon_0\), which allows to write any ordinal as an ordinal term \(\alpha\) following the abstract syntax

\[
\alpha ::= 0 \mid \omega^\alpha \mid \alpha + \alpha .
\]
Appendix A. Subrecursive Functions

We take here a reversed viewpoint: our interest lies not in the “set-theoretic” ordinals, but in the set \( \Omega \) of all ordinal terms. Each ordinal term \( \alpha \) is a syntactic object, and denotes a unique ordinal \( \text{ord}(\alpha) \) by interpretation into ordinal arithmetic, with \( + \) denoting direct sum. Using this interpretation, we can define a well-founded ordering on terms by \( \alpha' \leq \alpha \) if \( \text{ord}(\alpha') \leq \text{ord}(\alpha) \). Note that the mapping of terms to ordinals is not injective, so the ordering on terms is not antisymmetric.

In this reversed viewpoint, ordinal terms might be in CNF, i.e. sums

\[
\alpha = \omega^{\beta_1} + \cdots + \omega^{\beta_m}
\]

with \( \alpha > \beta_1 \geq \cdots \geq \beta_m \geq 0 \) with each \( \beta_i \) in CNF itself. We also use at times the strict form

\[
\alpha = \omega^{\beta_1} \cdot c_1 + \cdots + \omega^{\beta_m} \cdot c_m
\]

where \( \alpha > \beta_1 > \cdots > \beta_m \geq 0 \) and \( \omega > c_1, \ldots, c_m > 0 \) and each \( \beta_i \) in strict form—we call the \( c_i \)'s coefficients. Terms \( \alpha \) in CNF are in bijection with their denoted ordinals \( \text{ord}(\alpha) \). We write CNF(\( \alpha \)) for the set of ordinal terms \( \alpha' < \alpha \) in CNF; thus CNF(\( \varepsilon_0 \)) is a subset of \( \Omega \) in our view. Having a richer set \( \Omega \) will be useful later in Section A.8.¹

We write \( 1 \) for \( \omega^0 \) and \( \alpha \cdot n \) for \( \alpha + \cdots + \alpha \). We work modulo associativity \(((\alpha + \beta) + \gamma = \alpha + ((\beta + \gamma)) \) and idempotence \((\alpha + 0 = \alpha = 0 + \alpha) \) of \( + \). An ordinal term \( \alpha \) of form \( \gamma + 1 \) is called a successor ordinal term. Otherwise, if not 0, it is a limit ordinal term, usually denoted \( \lambda \). Note that a \( \text{ord}(0) = 0 \), \( \text{ord}(\alpha + 1) \) is a successor ordinal, and \( \text{ord}(\lambda) \) is a limit ordinal if \( \lambda \) is a limit ordinal term.

A.2 Fundamental Sequences and Predecessors

Fundamental Sequences. Subrecursive functions are defined through assignments of fundamental sequences \((\lambda_x)_{x<\omega}\) for limit ordinal terms \( \lambda \) in \( \Omega \), verifying \( \lambda_x < \lambda \) for all \( x \) in \( \mathbb{N} \) and \( \lambda = \sup_x \lambda_x \), i.e. we are interested in a particular sequence of terms of which \( \lambda \) is a limit.

A standard way of obtaining fundamental sequences with good properties for every limit ordinal term \( \lambda \) is to fix a particular sequence \((\omega_x)_{x<\omega}\) for \( \omega \) and to define

\[
(\gamma + \omega^{\beta+1})_x \overset{\text{def}}{=} \gamma + \omega^\beta \cdot \omega_x, \quad (\gamma + \omega^\lambda)_x \overset{\text{def}}{=} \gamma + \omega^\lambda \cdot x. \quad (A.1)
\]

We assume \( \omega_x \) to be the value in \( x \) of some monotone and expansive function \( s \), typically \( s(x) = x \)—which we will hold as the standard one—or \( s(x) = x + 1 \).

¹Richer ordinal notations can be designed, notably the structured ordinals of Dennis-Jones and Wainer (1984); Fairtlough and Wainer (1992) below \( \varepsilon_0 \), and of course richer notations are required in order to go beyond \( \varepsilon_0 \).
We will see in Section A.6 how different choices for \( \omega_x \) influence the hierarchies of functions built from them, in a simple case. Observe that, if \( s(x) > 0 \), then \( \lambda_x > 0 \).

**Predecessors.** Given an assignment of fundamental sequences and \( x \in \mathbb{N} \), one defines the (\( x \)-indexed) predecessor \( P_x(\alpha) < \alpha \) of an ordinal \( \alpha \neq 0 \) in \( \Omega \) as

\[
P_x(\alpha + 1) \overset{\text{def}}{=} \alpha, \quad P_x(\lambda) \overset{\text{def}}{=} P_x(\lambda_x).
\] (A.2)

**Lemma A.1.** Assume \( \alpha > 0 \) in \( \Omega \). Then for all \( x \in \mathbb{N} \) s.t. \( \omega_x > 0 \),

\[
P_x(\gamma + \alpha) = \gamma + P_x(\alpha), \quad P_x(\omega^\alpha) = \omega^{P_x(\alpha)} \cdot (\omega_x - 1) + P_x(\omega^{P_x(\alpha)}) .
\] (A.3)

**Proof of (A.3).** By induction over \( \alpha \). For the successor case \( \alpha = \beta + 1 \), this goes

\[
P_x(\gamma + \beta + 1) \overset{(A.2)}{=} \gamma + \beta \overset{(A.2)}{=} \gamma + P_x(\beta + 1) .
\]

For the limit case \( \alpha = \lambda \), this goes

\[
P_x(\gamma + \lambda) \overset{(A.2)}{=} P_x((\gamma + \lambda)_x) \overset{(A.1)}{=} P_x(\gamma + \lambda_x) \overset{\text{ih}}{=} \gamma + P_x(\lambda_x) \overset{(A.2)}{=} \gamma + P_x(\lambda) .
\] □

**Proof of (A.4).** By induction over \( \alpha \). For the successor case \( \alpha = \beta + 1 \), this goes

\[
P_x(\omega^{\beta+1}) \overset{(A.2)}{=} P_x((\omega^{\beta+1})_x) \overset{(A.1)}{=} P_x(\omega^{\beta} \cdot \omega_x) \overset{(A.3)}{=} \omega^\beta \cdot (\omega_x - 1) + P_x(\omega^\beta) \overset{(A.2)}{=} \omega^{P_x(\beta+1)} \cdot (\omega_x - 1) + P_x(\omega^{P_x(\beta+1)}) .
\]

For the limit case \( \alpha = \lambda \), this goes

\[
P_x(\omega^\lambda) \overset{(A.2)}{=} P_x((\omega^\lambda)_x) \overset{(A.1)}{=} P_x(\omega^{\lambda_x}) \overset{\text{ih}}{=} \omega^{P_x(\lambda_x)} \cdot (\omega_x - 1) + P_x(\omega^{P_x(\lambda_x)}) \overset{(A.2)}{=} \omega^{P_x(\lambda)} \cdot (\omega_x - 1) + P_x(\omega^{P_x(\lambda)}) .
\] □

### A.3 Pointwise Ordering and Lean Ordinals

**Pointwise ordering.** An issue with ordinal-indexed hierarchies is that they are typically not monotonic in their ordinal index. A way to circumvent this problem is to refine the ordinal ordering; an especially useful refinement is \( \prec_x \) defined for \( x \in \mathbb{N} \) as the smallest transitive relation satisfying (see Dennis-Jones and Wainer (1984); Fairtlough and Wainer (1992); Cichoń and Tahhan Bittar (1998)):

\[
\alpha \prec_x \alpha + 1 , \quad \lambda_x \prec_x \lambda .
\] (A.5)

In particular, using induction on \( \alpha \), one immediately sees that

\[
0 \preceq_x \alpha ,
\] (A.6)

\[
P_x(\alpha) \prec_x \alpha .
\] (A.7)
The inductive definition of $\prec_x$ implies
\[
\alpha' \prec_x \alpha \text{ iff } \begin{cases} 
\alpha = \beta + 1 \text{ is a successor and } \alpha' \prec_x \beta, \\
\alpha = \lambda \text{ is a limit and } \alpha' \preceq_x \lambda_x.
\end{cases}
\] (A.8)

Obviously $\prec_x$ is a restriction of $<$, the strict linear quasi-ordering over ordinal terms. For example, $\omega_x \prec_x \omega$ but $\omega_x + 1 \not\prec_x \omega$, although $\text{ord}(\omega_x + 1)$ is by definition a finite ordinal, smaller than $\text{ord}(\omega)$.

The $\prec_x$ relations are linearly ordered themselves
\[
\prec_0 \subseteq \cdots \subseteq \prec_x \subseteq \prec_{x+1} \subseteq \cdots
\] (A.9)

and, over terms in CNF, $<$ can be recovered by
\[
\left( \bigcup_{x \in \mathbb{N}} \prec_x \right) = <.
\] (A.10)

We will soon prove these results in Corollary A.4 and Lemma A.5, but we need first some basic properties of $\prec_x$.

**Lemma A.2.** For all $\alpha, \alpha', \gamma$ in $\Omega$ and all $x$ in $\mathbb{N}$

\[
\alpha' \prec_x \alpha \text{ implies } \gamma + \alpha' \prec_x \gamma + \alpha, \] (A.11)

\[
\omega_x > 0 \text{ and } \alpha' \prec_x \alpha \text{ imply } \omega^{\alpha'} \prec_x \omega^{\alpha}. \] (A.12)

**Proof.** All proofs are by induction over $\alpha$ (NB: the case $\alpha = 0$ is impossible).

(A.11): For the successor case $\alpha = \beta + 1$, this goes through
\[
\alpha' \prec_x \beta + 1 \text{ implies } \alpha' \preceq_x \beta \quad \text{(by (A.8))}
\]
implies $\gamma + \alpha' \preceq_x \gamma + \beta$ (A.5) (by ind. hyp.)

For the limit case $\alpha = \lambda$, this goes through
\[
\alpha' \prec_x \lambda \text{ implies } \alpha' \preceq_x \lambda_x \quad \text{(by (A.8))}
\]
implies $\gamma + \alpha' \preceq_x \gamma + \lambda_x$ (A.1) (A.5) (by ind. hyp.)

(A.12): For the successor case $\alpha = \beta + 1$, we go through
\[
\alpha' \prec_x \beta + 1 \text{ implies } \alpha' \preceq_x \beta \quad \text{(by (A.8))}
\]
implies $\omega^{\alpha'} \preceq_x \omega^\beta = \omega^\beta + 0$ (by ind. hyp.)
implies $\omega^{\alpha'} \preceq_x \omega^\beta + \omega^\beta \cdot (\omega_x - 1)$ (by equations (A.6) and (A.11))
implies $\omega^{\alpha'} \preceq_x \omega^\beta \cdot \omega_x = (\omega^\beta + 1)_x \preceq_x \omega^{\beta+1}$.
For the limit case $\alpha = \lambda$, this goes through
\[ \alpha' \prec^x \lambda \text{ implies } \alpha' \prec^x \lambda_x \] (by (A.8))
implies $\omega^{\alpha'} \prec^x \omega^{\lambda_x} \equiv (\omega^\lambda)^x (A.5)$ (A.5)
(by ind. hyp.)

Lemma A.2 shows that $\prec^x$ is left congruent for + and congruent for $\omega$-exponentiation. One can observe that it is not right congruent for +; consider for instance the terms $\omega_x + 1$ and $\omega + 1$: one can see that $\omega_x + 1 \not\prec^x \omega + 1$. Indeed, from $\omega + 1$ the only way of descending through $\prec^x$ is $\omega + 1 \succ^x \omega \succ^x \omega_x$, but $\omega_x \not\prec^x \omega_x + 1$ since $\prec^x \subseteq \prec$ for terms in $\text{CNF}(\varepsilon_0)$.

**Lemma A.3.** Let $\lambda$ be a limit ordinal in $\Omega$ and $x < y$ in $\mathbb{N}$. Then $\lambda_x \preceq^y \lambda_y$, and if furthermore $\omega_x > 0$, then $\lambda_x \preceq^x \lambda_y$.

**Proof.** By induction over $\lambda$. Write $\omega_y = \omega_x + z$ for some $z \geq 0$ by monotonicity of $s$ (recall that $\omega_x$ and $\omega_y$ are in $\mathbb{N}$) and $\lambda = \gamma + \omega^\alpha$ with $0 < \alpha$.

If $\alpha = \beta + 1$ is a successor, then $\lambda_x = \gamma + \omega^\beta \cdot \omega_x \preceq^y \gamma + \omega^\beta \cdot \omega_x + \omega^\beta \cdot z$ by (A.11) since $0 \preceq^y \omega^\beta \cdot z$. We conclude by noting that $\lambda_y = \gamma + \omega^\beta \cdot (\omega_x + z)$; the same arguments also show $\lambda_x \preceq^x \lambda_y$.

If $\alpha$ is a limit ordinal, then $\alpha_x \preceq^y \alpha_y$ by ind. hyp., hence $\lambda_x = \gamma + \omega^{\alpha_x} \preceq^y \gamma + \omega^{\alpha_y} = \lambda_y$ by (A.12) (applicable since $\omega_y \geq x \geq y \geq 0$) and (A.11). If $\omega_x > 0$, then the same arguments show $\lambda_x \preceq^x \lambda_y$.

Now, using (A.8) together with Lemma A.3, we see

**Corollary A.4.** Let $\alpha, \beta$ in $\Omega$ and $x, y$ in $\mathbb{N}$. If $x \leq y$ then $\alpha \prec^x \beta$ implies $\alpha \prec^y \beta$.

In other words, $\prec^x \subseteq \prec^{x+1} \subseteq \prec^{x+2} \subseteq \cdots$ as claimed in (A.9).

If $s$ is strictly increasing, i.e. if $\omega_x < \omega_{x+1}$ for all $x$, then the statement of Lemma A.3 can be strengthened to $\lambda_x \prec^y \lambda_y$ and $\lambda_y \prec^x \lambda_y$ when $\omega_x > 0$, and this hierarchy becomes strict at every level $x$: indeed, $\omega_{x+1} \prec^x \omega$ but $\omega_{x+1} \prec^x \omega$ would imply $\omega_{x+1} \preceq^x \omega_x$, contradicting $\prec^x \subseteq \prec$.

**Lean Ordinals.** Let $k$ be in $\mathbb{N}$. We say that an ordinal $\alpha$ in $\text{CNF}(\varepsilon_0)$ is $k$-lean if it only uses coefficients $\leq k$, or, more formally, when it is written under the strict form $\alpha = \omega^\beta_1 \cdot c_1 + \cdots + \omega^\beta_m \cdot c_m$ with $c_i \leq k$ and, inductively, with $k$-lean $\beta_i$, this for all $i = 1, \ldots, m$. Observe that only 0 is 0-lean, and that any term in $\text{CNF}$ is $k$-lean for some $k$.

A value $k$ of particular importance for lean ordinal terms is $k = \omega_x - 1$: observe that this is the coefficient value introduced when we compute a predecessor ordinal at $x$. Stated differently, $(\omega_x - 1)$-leaness is an invariant of predecessor computations: if $\alpha$ is $(\omega_x - 1)$-lean, then $P_x(\alpha)$ is also $(\omega_x - 1)$-lean.

Leaness also provides a very useful characterization of the $\prec^x$ relation in terms of the ordinal ordering over terms in $\text{CNF}$:
Lemma A.5. Let $x$ be in $\mathbb{N}$, and $\alpha$ in $\text{CNF}(\varepsilon_0)$ be $(\omega_x - 1)$-lean. Then:

$$\alpha < \gamma \iff \alpha \prec_x \gamma \iff \alpha \preceq_x P_x(\gamma) \iff \alpha \leq P_x(\gamma).$$

(A.13)

One sees $\left( \bigcup_{x \in \mathbb{N}} \prec_x \right) = < $ over terms in $\text{CNF}(\varepsilon_0)$ as a result of Lemma A.5. The proof relies on the syntactic characterization of the ordinal ordering over terms in $\text{CNF}(\varepsilon_0)$ by

$$\alpha < \alpha' \iff \begin{cases} \alpha = 0 \text{ and } \alpha' \neq 0, \text{ or} \\ \alpha = \omega^\beta + \gamma, \alpha' = \omega^\beta' + \gamma' \text{ and} \\ \beta < \beta', \text{ or} \\ \beta = \beta' \text{ and } \gamma < \gamma'. \end{cases}$$

(A.14)

Since $\alpha \preceq_x P_x(\gamma)$ directly entails all the other statements of Lemma A.5, it is enough to prove:

Claim A.5.1. Let $\alpha, \gamma$ in $\text{CNF}(\varepsilon_0)$ and $x$ in $\mathbb{N}$. If $\alpha$ is $(\omega_x - 1)$-lean, then

$$\alpha < \gamma \text{ implies } \alpha \preceq_x P_x(\gamma).$$

Proof. If $\alpha = 0$, we are done so we assume $\alpha > 0$ and hence $\omega_x > 1$, thus $\alpha = \sum_{i=1}^{m} \omega_i \cdot c_i$ with $m > 0$. Working with terms in CNF allows us to employ the syntactic characterization of $<$ given in (A.14).

We prove the claim by induction on $\gamma$, considering two cases:

1. if $\gamma = \gamma' + 1$ is a successor then $\alpha < \gamma$ implies $\alpha \leq \gamma'$, hence $\alpha \preceq_x \gamma' \overset{(A.2)}{=} P_x(\gamma)$.

2. if $\gamma$ is a limit, we claim that $\alpha < \gamma_x$, from which we deduce $\alpha \preceq_x P_x(\gamma_x) \overset{(A.2)}{=} P_x(\gamma)$. We consider three subcases for the claim:

   (a) if $\gamma = \omega^\lambda$ with $\lambda$ a limit, then $\alpha = \sum_{i=1}^{m} \omega_i \cdot c_i < \gamma$ implies $\beta_1 < \lambda$, hence $\beta_1 \preceq_x P_x(\lambda) = P_x(\lambda_x) < \lambda_x$, since $\beta_1$ is $(\omega_x - 1)$-lean. Thus $\alpha < \omega^\lambda_x = (\omega^\lambda)_x = \gamma_x$.

   (b) if $\gamma = \omega^\beta + 1$ then $\alpha < \gamma$ implies $\beta_1 < \beta + 1$, hence $\beta_1 \leq \beta$. Now $c_1 \leq \omega_x - 1$ since $\alpha$ is $(\omega_x - 1)$-lean, hence $\alpha < \omega^\beta_1 \cdot (c_1 + 1) \leq \omega^\beta \cdot \omega_x \leq \omega^\beta \cdot \omega_x = (\omega^\beta + 1)_x = \gamma_x$.

   (c) if $\gamma = \gamma' + \omega^\beta$ with $0 < \gamma', \beta$, then either $\alpha \leq \gamma'$, hence $\alpha < \gamma' + (\omega^\beta)_x = \gamma_x$, or $\alpha > \gamma'$, and then $\alpha$ can be written as $\alpha = \gamma' + \alpha'$ with $\alpha' < \omega^\beta$. In that case $\alpha' \preceq_x P_x(\omega^\beta) \overset{(A.2)}{=} P_x((\omega^\beta)_x) < (\omega^\beta)_x$, hence $\alpha = \gamma' + \alpha' \preceq \gamma' + (\omega^\beta)_x = (\gamma' + \omega^\beta)_x = \gamma_x$. \qed
A.4 Ordinal Indexed Functions

Let us recall several classical hierarchies from Cichoń and Wainer [1983; Cichoń and Tahhan Bittar, 1998]. All the functions we define are over natural numbers. We introduce "relativized" versions of the hierarchies, which employ a unary control function $h : \mathbb{N} \to \mathbb{N}$; the “standard” hierarchies then correspond to the special case where the successor function $h(x) = x + 1$ is picked. We will see later in Section A.7 how hierarchies with different control functions can be related.

Hardy Functions. We define the functions $(h^\alpha)_{\alpha \in \Omega}$, each $h^\alpha : \mathbb{N} \to \mathbb{N}$, by inner iteration:

$$h^0(x) \overset{\text{def}}{=} x, \quad h^{\alpha+1}(x) \overset{\text{def}}{=} h^\alpha(h(x)), \quad h^\lambda(x) \overset{\text{def}}{=} h^{\lambda_x}(x). \quad \text{(A.15)}$$

An example of inner iteration hierarchy is the Hardy hierarchy $(H^\alpha)_{\alpha \in \Omega}$ obtained from (A.15) in the special case of $h(x) = x + 1$:

$$H^0(x) \overset{\text{def}}{=} x, \quad H^{\alpha+1}(x) \overset{\text{def}}{=} H^\alpha(x + 1), \quad H^\lambda(x) \overset{\text{def}}{=} H^{\lambda_x}(x). \quad \text{(A.16)}$$

Cichoń Functions. Again for a unary $h$, we can define a variant $(h^\alpha)_{\alpha \in \Omega}$ of the Hardy functions called the length hierarchy by Cichoń and Tahhan Bittar [1998] and defined by inner and outer iteration:

$$h_0(x) \overset{\text{def}}{=} 0, \quad h_{\alpha+1}(x) \overset{\text{def}}{=} 1 + h_\alpha(h(x)), \quad h_\lambda(x) \overset{\text{def}}{=} h_{\lambda_x}(x). \quad \text{(A.17)}$$

As before, in the case where $h(x) = x + 1$ is the successor function, this yields

$$H_0(x) \overset{\text{def}}{=} 0, \quad H_{\alpha+1}(x) \overset{\text{def}}{=} 1 + H_\alpha(x + 1), \quad H_\lambda(x) \overset{\text{def}}{=} H_{\lambda_x}(x). \quad \text{(A.18)}$$

Those hierarchies are the most closely related to the hierarchies of functions we define for the length of bad sequences.

Fast Growing Functions. Last of all, the fast growing functions $(f^\alpha)_{\alpha \in \Omega}$ are defined through

$$f_0(x) \overset{\text{def}}{=} h(x), \quad f_{\alpha+1}(x) \overset{\text{def}}{=} f^{\omega_x}(x), \quad f_\lambda \overset{\text{def}}{=} f_{\lambda_x}(x), \quad \text{(A.19)}$$

while its standard version (for $h(x) = x + 1$) is defined by

$$F_0(x) \overset{\text{def}}{=} x + 1, \quad F_{\alpha+1}(x) \overset{\text{def}}{=} F^{\omega_x}(x), \quad F_\lambda \overset{\text{def}}{=} F_{\lambda_x}(x). \quad \text{(A.20)}$$

Several properties of these functions can be proved by rather simple induction arguments.

Lemma A.5. For all $\alpha > 0$ in $\Omega$ and $x$ in $\mathbb{N}$ with $\omega_X > 0$,

$$h_\alpha(x) = 1 + h_{P_x(\alpha)}(h(x)) \quad \text{(A.21)}$$

$$h^\alpha(x) = h^{P_x(\alpha)}(h(x)) = h^{P_x(\alpha)+1}(x) \quad \text{(A.22)}$$

$$f_\alpha(x) = f^{\omega_x}_{P_x(\alpha)}(x) = f^{P_x(\alpha)+1}(x). \quad \text{(A.23)}$$
Proof. We only prove \((A.21); (A.22)\) and \((A.23)\) can be proven similarly.

By transfinite induction over \(\alpha\). For a successor ordinal \(\alpha + 1\), \(h_{\alpha+1}(x) = 1 + h_{\alpha}(h(x)) \equiv 1 + h_{P_x}(\alpha+1)(h(x)).\) For a limit ordinal \(\lambda\), \(h_{\lambda}(x) = h_{\lambda_x}(x) \equiv 1 + h_{P_x}(\lambda)(h(x))\), where the ind. hyp. can applied since \(0 < \lambda_x < \lambda\).

\(\square\)

**Lemma A.6.** Let \(h(x) > x\) for all \(x\). Then for all \(\alpha\) in \(\Omega\) and \(x\) in \(\mathbb{N}\) with \(\omega_x > 0\),
\[ h_\alpha(x) \leq h^\alpha(x) - x. \]

**Proof.** By induction over \(\alpha\). For \(\alpha = 0\), \(h_0(x) = 0 = x - x = h^0(x) - x.\) For \(\alpha > 0,\)
\[
\begin{align*}
h_\alpha(x) &= 1 + h_{P_x}(\alpha)(h(x)) \quad \text{(by Lemma A.5)} \\
&\leq 1 + h_{P_x}(\alpha)(h(x)) - h(x) \quad \text{(by ind. hyp. since } P_x(\alpha) < \alpha) \\
&\leq h_{P_x}(\alpha)(h(x)) - x \quad \text{(since } h(x) > x) \\
&= h^\alpha(x) - x. \quad \text{(by } \text{(A.22)})
\end{align*}
\]

\(\square\)

Using the same argument, one can check that in particular for \(h(x) = x + 1,\)
\[ H_\alpha(x) = H^\alpha(x) - x. \tag{A.24} \]

**Lemma A.7.** For all \(\alpha, \gamma\) in \(\Omega\), and \(x,\)
\[ h^{\gamma+\alpha}(x) = h^\gamma(h^\alpha(x)). \]

**Proof.** By transfinite induction on \(\alpha\). For \(\alpha = 0\), \(h^{\gamma+0}(x) = h^\gamma(x) = h^\gamma(h^0(x)).\)

For a successor ordinal \(\alpha + 1\), \(h^{\gamma+\alpha+1}(x) = h^{\gamma+\alpha}(h(x)) \equiv h^\gamma(h^\alpha(h(x))) = h^\gamma(h^{\alpha+1}(x)).\) For a limit ordinal \(\lambda\), \(h^{\gamma+\lambda}(x) = h^{(\gamma+\lambda)x}(x) = h^{\gamma+\lambda_x}(x) \equiv h^\gamma(h^{\lambda_x}(x)).\)

\(\square\)

**Remark A.8.** Some care should be taken with \(\text{Lemma A.7; } \gamma + \alpha\) is not necessarily a term in CNF. See \(\text{Remark A.14 on page 80}\) for a related discussion.

**Lemma A.9.** For all \(\beta\) in \(\Omega\), and \(r, x\) in \(\mathbb{N},\)
\[ h^{\omega^\beta r}(x) = f^r_\beta(x). \]

**Proof.** In view of \(\text{Lemma A.7}\) and \(h^0 = f^0 = Id_{\mathbb{N}},\) it is enough to prove \(h^{\omega^\beta} = f_\beta,\) i.e., the \(r = 1\) case. We proceed by induction over \(\beta.\)

For the base case. \(h^{\omega^0}(x) = h^1(x) \equiv f_0(x).\)

For a successor \(\beta + 1.\) \(h^{\omega^{\beta+1}}(x) \equiv h^{(\omega^{\beta+1})x}(x) = h^{\omega^{\beta} \cdot \omega_x}(x) \equiv f^{\omega_x}_\beta(x) \equiv f_{\beta+1}(x).\)

For a limit \(\lambda.\) \(h^{\omega^\lambda}(x) \equiv h^{\omega^{\lambda_x}}(x) \equiv f_{\lambda_x}(x) \equiv f_\lambda(x).\)

\(\square\)
A.5 Pointwise Ordering and Monotonicity

We set to prove in this section the main monotonicity and expansiveness properties of our various hierarchies.

Lemma A.10 (Cichoń and Tahhan Bittar, 1998). Let $h$ be an expansive monotone function. Then, for all $\alpha, \alpha' \in \Omega$ and $x, y \in \mathbb{N}$,

\begin{align*}
x < y & \implies h_\alpha(x) \leq h_\alpha(y), \quad (A.25) \\
\alpha' \prec_x \alpha & \implies h_{\alpha'}(x) \leq h_\alpha(x). \quad (A.26)
\end{align*}

Proof. Let us first deal with $\alpha' = 0$ for (A.26). Then $h_0(x) = 0 \leq h_\alpha(x)$ for all $\alpha$ and $x$.

Assuming $\alpha' > 0$, the proof now proceeds by simultaneous transfinite induction over $\alpha$.

For 0. Then $h_0(x) = 0 = h_0(y)$ and (A.26) holds vacuously since $\alpha' \prec_x \alpha$ is impossible.

For a successor $\alpha + 1$. For (A.25), $h_{\alpha + 1}(x) = 1 + h_\alpha(h(x)) \leq 1 + h_\alpha(h(y)) = h_{\alpha + 1}(y)$ where the ind. hyp. on (A.25) can be applied since $h$ is monotone.

For (A.26), we have $\alpha' \preceq_x \alpha \prec_x \alpha + 1$, hence $h_{\alpha'}(x) \leq h_\alpha(x) \leq h_{\alpha + 1}(x)$ where the ind. hyp. on (A.25) can be applied since $h(x) \geq x$.

For a limit $\lambda$. For (A.25), $h_{\lambda}(x) = h_{\lambda_x}(x) \leq h_{\lambda_y}(y) = h_{\lambda}(y)$ where the ind. hyp. on (A.26) can be applied since $\lambda_x \prec_y \lambda_y$ by Lemma A.3.

For (A.26), we have $\alpha' \preceq_x \lambda_x \prec_x \lambda$ with $h_{\alpha'}(x) \leq h_{\lambda_x}(x) = h_{\lambda}(x)$.

Essentially the same proof can be carried out to prove the same monotonicity properties for $h^\alpha$ and $f_\alpha$. As the monotonicity properties of $f_\alpha$ will be handy in the remainder of the section, we prove them now:

Lemma A.11 (Löb and Wainer, 1970). Let $h$ be a function with $h(x) \geq x$. Then, for all $\alpha, \alpha' \in \Omega$, $x, y \in \mathbb{N}$ with $\omega_x > 0$,

\begin{align*}
f_\alpha(x) & \geq h(x) \geq x, \quad (A.27) \\
\alpha' \prec_x \alpha & \implies f_{\alpha'}(x) \leq f_\alpha(x), \quad (A.28) \\
x < y & \text{ and } h \text{ monotone imply } f_\alpha(x) \leq f_\alpha(y). \quad (A.29)
\end{align*}
Proof of (A.27). By transfinite induction on $\alpha$. For the base case, $f_0(x) = h(x) \geq x$ by hypothesis. For the successor case, assuming $f_\alpha(x) \geq h(x)$, then by induction on $n > 0$, $f_\alpha^n(x) \geq h(x)$: for $n = 1$ it holds since $f_\alpha(x) \geq h(x)$, and for $n + 1$ since $f_\alpha^{n+1}(x) = f_\alpha(f_\alpha^n(x)) \geq f_\alpha(x)$ by ind. hyp. on $n$. Therefore $f_{\alpha+1}(x) = f_\alpha^{\omega_x}(x) \geq x$ since $\omega_x > 0$. Finally, for the limit case, $f_\lambda(x) = f_{\lambda_x}(x) \geq x$ by ind. hyp.

Proof of (A.28). Let us first deal with $\alpha' = 0$. Then $f_0(x) = h(x) \leq f_\alpha(x)$ for all $x > 0$ and all $\alpha$ by (A.27).

Assuming $\alpha' > 0$, the proof proceeds by transfinite induction over $\alpha$. The case $\alpha = 0$ is impossible. For the successor case, $\alpha' \leq x \alpha \prec x \alpha + 1$ with $f_{\alpha+1}(x) = f_\alpha^{\omega_x-1}(f_\alpha(x)) \geq f_\alpha(x) \geq f_\alpha'(x)$. For the limit case, we have $\alpha' \leq x \lambda_x \prec x \lambda$ with $f_{\alpha'}(x) \leq f_{\lambda_x}(x) = f_\lambda(x)$.

Proof of (A.29). By transfinite induction over $\alpha$. For the base case, $f_0(x) = h(x) \leq h(y) = f_0(y)$ since $h$ is monotone. For the successor case, $f_{\alpha+1}(x) = f_\alpha^{\omega_x}(x) \leq f_\alpha^{\omega_y}(x) \leq f_{\alpha+1}(y) = f_\alpha^{\omega}(y) = f_{\alpha+1}(y)$ using $\omega_x \leq \omega_y$. For the limit case, $f_\lambda(x) = f_{\lambda_x}(x) \leq f_{\lambda_y}(y) \leq f_\lambda(y)$, where (A.28) can be applied thanks to Lemma A.3.

A.6 Different Fundamental Sequences

The way we employ ordinal-indexed hierarchies is as standard ways of classifying the growth of functions, allowing to derive meaningful complexity bounds for algorithms relying on wqos for termination. It is therefore quite important to use a standard assignment of fundamental sequences in order to be able to compare results from different sources. The definition provided in (A.1) is standard, and the two choices $\omega_x = x$ and $\omega_x = x + 1$ can be deemed as “equally standard” in the literature. We employed $\omega_x = x + 1$ in the rest of the notes, but the reader might desire to compare this to bounds using e.g. $\omega_x = x$—as seen in Lemma A.12, this is possible for strictly increasing $h$.

A bit of extra notation is needed: we want to compare the Cichoń hierarchies $(h_{s,\alpha})_{\alpha \in \Omega}$ for different choices of $s$. Recall that $s$ is assumed to be monotone and expansive, which is true of the identity function $id$.

Lemma A.12. Let $\alpha \in \Omega$. If $s(h(x)) \leq h(s(x))$ for all $x$, then $h_{s,\alpha}(x) \leq h_{id,\alpha}(s(x))$ for all $x$.

Proof. By induction on $\alpha$. For $0$, $h_{s,0}(x) = 0 = h_{id,0}(s(x))$. For a successor ordinal $\alpha + 1$, $h_{s,\alpha+1}(x) = 1 + h_{s,\alpha}(h(x)) \leq 1 + h_{id,\alpha}(s(h(x))) \leq 1 + h_{id,\alpha}(h(s(x))) = h_{id,\alpha+1}(s(x))$ since $s(h(x)) \leq h(s(x))$. For a limit ordinal
\[ \lambda, h_{s,\lambda}(x) = h_{s,\lambda_x}(x) \leq h_{id,\lambda_x}(s(x)) \leq h_{id,\lambda_{x}(s(x))} = h_{id,\lambda}(s(x)) \] where \( s(x) \geq x \) implies \( \lambda_x \prec_{s(x)} \lambda_{s(x)} \) by Lemma A.3 and allows to apply (A.26). \( \square \)

A simple corollary of Lemma A.12 for \( s(x) = x + 1 \) is that, if \( h \) is strictly monotone, then \( h(x + 1) \geq 1 + h(x) \), and thus \( h_{s,\alpha}(x) \leq h_{id,\alpha}(x + 1) \), i.e. the Cichoń functions for the two classical assignments of fundamental sequences are tightly related and will always fall in the same classes of subrecursive functions. This also justifies not giving too much importance to the choice of \( s \)—within reasonable limits.

## A.7 Different Control Functions

As in Section A.6, if we are to obtain bounds in terms of a standard hierarchy of functions, we ought to provide bounds for \( h(x) = x + 1 \) as control. We are now in position to prove a statement of Cichoń and Wainer (1983):

**Lemma A.13.** For all \( \gamma \) and \( \alpha \) in \( \Omega \), if \( h \) is monotone eventually dominated by \( F_\gamma \), then \( f_\alpha \) is eventually dominated by \( F_{\gamma+\alpha} \).

**Proof.** By hypothesis, there exists \( x_0 \) (which we can assume wlog. verifies \( x_0 > 0 \)) s.t. for all \( x \geq x_0 \), \( h(x) \leq F_\gamma(x) \). We keep this \( x_0 \) constant and show by transfinite induction on \( \alpha \) that for all \( x \geq x_0 \), \( f_\alpha(x) \leq F_{\gamma+\alpha}(x) \), which proves the lemma. Note that \( \omega_x \geq x \geq x_0 > 0 \) and thus that we can apply Lemma A.11.

For the base case \( 0 \): for all \( x \geq x_0 \), \( f_0(x) = h(x) \leq F_\gamma(x) \) by hypothesis.

For a successor ordinal \( \alpha + 1 \): we first prove that for all \( n \) and all \( x \geq x_0 \),

\[ f_\alpha^n(x) \leq F_{\gamma+\alpha}^n(x). \] (A.30)

Indeed, by induction on \( n \), for all \( x \geq x_0 \),

\[ f_\alpha^0(x) = x = F_{\gamma+\alpha}^0(x) \]

\[ f_\alpha^{n+1}(x) = f_\alpha(f_\alpha^n(x)) \]

\[ \leq f_\alpha(F_{\gamma+\alpha}^n(x)) \quad \text{(by (A.29) on } f_\alpha \text{ and the ind. hyp. on } n) \]

\[ \leq F_{\gamma+\alpha}(F_{\gamma+\alpha}^n(x)) \quad \text{(since by (A.27) } F_{\gamma+\alpha}(x) \geq x \geq x_0 \text{ and by ind. hyp. on } \alpha) \]

\[ = F_{\gamma+\alpha}^{n+1}(x). \]

Therefore

\[ f_{\alpha+1}(x) = f_\alpha^x(x) \]

\[ \leq F_{\gamma+\alpha}^x(x) \quad \text{(by (A.30) for } n = x) \]

\[ = F_{\gamma+\alpha+1}(x). \]
For a limit ordinal $\lambda$: for all $x \geq x_0$, $f_\lambda(x) = f_{\lambda_0}(x) \leq F_{\gamma+\lambda_0}(x) = F_{(\gamma+\lambda)_0}(x) = F_{\gamma+\lambda}(x)$. \hfill $\square$

Remark A.14. Observe that the statement of Lemma A.13 is one of the few instances in this appendix where ordinal term notations matter. Indeed, nothing forces $\gamma + \alpha$ to be an ordinal term in CNF. Note that, with the exception of Lemma A.5, all the definitions and proofs given in this appendix are compatible with arbitrary ordinal terms in $\Omega$, and not just terms in CNF, so this is not a formal issue.

The issue lies in the intuitive understanding the reader might have of a term “$\gamma + \alpha$”, by interpreting $+$ as the direct sum in ordinal arithmetic. This would be a mistake: in a situation where two different terms $\alpha$ and $\alpha'$ denote the same ordinal $\text{ord}(\alpha) = \text{ord}(\alpha')$, we do not necessarily have $F_\alpha(x) = F_{\alpha'}(x)$: for instance, $\alpha = \omega^\omega$ and $\alpha' = \omega^0 + \omega^\omega$ denote the same ordinal $\omega$, but $F_\alpha(2) = F_\alpha(2) = 2^2 \cdot 2 = 3$ and $F_{\alpha'}(2) = F_{\beta'}(2) = 2^{2^2} \cdot 2^2 \cdot 2 = 2^{11}$. Therefore, the results on ordinal-indexed hierarchies in this appendix should be understood syntactically on ordinal terms, and not semantically on their ordinal denotations.

The natural question at this point is: how do these new fast growing functions compare to the functions indexed by terms in CNF? Indeed, we should check that e.g. $F_{\gamma+\omega^\omega}$ with $\gamma < \omega^\omega$ is multiply-recursive if our results are to be of any use. The most interesting case is the one where $\gamma$ is finite but $\alpha$ infinite (which will be used in the proof of Lemma A.16):

**Lemma A.15.** Let $\alpha \geq \omega$ and $0 < \gamma < \omega$ be in $\text{CNF}(\varepsilon_0)$, and $\omega_x \overset{\text{def}}{=} x$. Then, for all $x$, $F_{\gamma+\alpha}(x) \leq F_\alpha(x + \gamma)$.

**Proof.** We first show by induction on $\alpha \geq \omega$ that

Claim A.15.1. Let $s(x) \overset{\text{def}}{=} x + \gamma$. Then for all $x$, $F_{\text{id},\gamma+\alpha}(x) \leq F_{s,\alpha}(x)$.

**base case for $\omega$:** $F_{\text{id},\gamma+\omega}(x) = F_{\text{id},\gamma+x}(x) = F_{s,\omega}(x)$,

**successor case $\alpha+1$:** with $\alpha \geq \omega$, an induction on $n$ shows that $F_{\text{id},\gamma+\alpha}(x) \leq F_{s,\alpha}(x)$ for all $n$ and $x$ using the ind. hyp. on $\alpha$, thus $F_{\text{id},\gamma+\alpha+1}(x) = F_{\text{id},\gamma+\alpha}(x) \leq F_{s,\alpha+1}(x)$.

**limit case $\lambda > \omega$:** $F_{\text{id},\gamma+\lambda}(x) = F_{\text{id},\gamma+\lambda_0}(x) \leq F_{s,\lambda_0}(x) \leq F_{s,\lambda} \overset{(A.28)}{=} F_{s,\lambda_x} \overset{(A.28)}{=} F_{s,\lambda_x+\gamma}(x)$ where (A.28) can be applied since $\lambda_x \leq \lambda x + \gamma$ by Lemma A.3 (applicable since $s(x) = x + \gamma > 0$).

Returning to the main proof, note that $s(x + 1) = x + 1 + \gamma = s(x) + 1$,
allowing to apply Lemma A.12, thus for all \( x \),

\[
F_{id,\gamma+\alpha}(x) \leq F_{\alpha}(x) = H_s^{\omega_\alpha}(x) \leq H^{\omega_\alpha}(s(x)) = F_{id,\alpha}(s(x)).
\]

(by the previous claim)  

(by Lemma A.9)  

(by Lemma A.12 and (A.24))  

(by Lemma A.9)

\[\square\]

A.8 Classes of Subrecursive Functions

We finally consider how some natural classes of recursive functions can be characterized by closure operations on subrecursive hierarchies. The best-known of these classes is the extended Grzegorczyk hierarchy \( (\mathcal{F}_\alpha)_{\alpha \in \text{CNF}(e_0)} \) defined by Löb and Wainer (1970) on top of the fast-growing hierarchy \( (F_\alpha)_{\alpha \in \text{CNF}(e_0)} \) for \( \omega_x \leq x \).

Let us first provide some background on the definition and properties of \( \mathcal{F}_\alpha \). The class of functions \( \mathcal{F}_\alpha \) is the closure of the constant, addition, projection (including identity), and \( F_\alpha \) functions, under the operations of

\begin{itemize}
  \item \textbf{substitution}: if \( h_0, h_1, \ldots, h_n \) belong to the class, then so does the function \( f \) defined by
    \[
    f(x_1, \ldots, x_n) = h_0(h_1(x_1, \ldots, x_n), \ldots, h_n(x_1, \ldots, x_n)),
    \]
  
  \item \textbf{limited primitive recursion}: if \( h_1, h_2, \) and \( h_3 \) belong to the class, then so does the function \( f \) defined by
    \[
    f(0, x_1, \ldots, x_n) = h_1(x_1, \ldots, x_n),
    f(y + 1, x_1, \ldots, x_n) = h_2(y, x_1, \ldots, x_n, f(y, x_1, \ldots, x_n)),
    f(y, x_1, \ldots, x_n) \leq h_3(y, x_1, \ldots, x_n).
    \]
\end{itemize}

The hierarchy is strict for \( \alpha > 0 \), i.e. \( \mathcal{F}_{\alpha'} \subset \mathcal{F}_\alpha \) if \( \alpha' < \alpha \), because in particular \( F_{\alpha'} \notin \mathcal{F}_\alpha \). For small finite values of \( \alpha \), the hierarchy characterizes some well-known classes of functions:

\begin{itemize}
  \item \( \mathcal{F}_0 = \mathcal{F}_1 \) contains all the linear functions, like \( \lambda x.x + 3 \) or \( \lambda x.2x \), along with many simple ones like \textbf{cut-off subtraction}: \( \lambda xy.x - y \), which yields \( x - y \) if \( x \geq y \) and 0 otherwise.\(^3\)
  \item or simple predicates like \textbf{odd}: \( \lambda x.x \mod 2 = 0\).\(^4\)
  
  \item \( \mathcal{F}_2 \) is exactly the set of elementary functions, like \( \lambda x.2^x \).
\end{itemize}

\(^3\)By limited primitive recursion: first define \( \lambda x.x \div 1 \) by \( 0 \div 1 = 0 \) and \( (y + 1) \div 1 = y \); then \( x \div 0 = x \) and \( x \div (y + 1) = (x \div y) \div 1 \).

\(^4\)By limited primitive recursion: \( 0 \mod 2 = 0 \) and \( (y + 1) \mod 2 = 1 \div (y \mod 2) \).
Appendix A. Subrecursive Functions

- \( F_3 \) contains all the tetration functions, like \( \lambda x. 2^{2^{\ldots^2}} \), etc.

The union \( \bigcup_{\alpha < \omega} F_\alpha \) is the set of primitive-recursive functions, while \( F_\omega \) is an Ackermann-like non primitive-recursive function. Similarly, \( \bigcup_{\alpha < \omega} F_\alpha \) is the set of multiply-recursive functions with \( F_\omega \) a non multiply-recursive function.

The following properties (resp. Theorem 2.10 and Theorem 2.11 in [Löb and Wainer, 1970]) are useful: for all \( \alpha, \) unary \( f \) in \( F_\alpha \), and \( x \),

\[
\begin{align*}
\alpha > 0 & \text{ implies } \exists p, \ f(x) \leq F^p_\alpha(x + 1) , \\
\exists p, \ \forall x \geq p, \ f(x) \leq F_{\alpha+1}(x) .
\end{align*}
\tag{A.31}
\tag{A.32}
\]

Also note that by (A.31), if a unary function \( g \) is dominated by some function \( g' \) in \( F_\alpha \) with \( \alpha > 0 \), then there exists \( p \) s.t. for all \( x \), \( g(x) \leq g'(x) \leq F^p_\alpha(x + 1) \). Similarly, (A.32) shows that for all \( x \geq p \), \( g(x) \leq g'(x) \leq F_{\alpha+1}(x) \).

Let us conclude this appendix with the following lemma, which shows that the difficulties raised by non-CNF ordinal terms (recall Remark A.14) are alleviated when working with the \( (F_\alpha)_\alpha \):

**Lemma A.16.** For all \( \gamma > 0 \) and \( \alpha \), if \( h \) is monotone and eventually dominated by a function in \( F_\gamma \), then

1. if \( \alpha < \omega \), \( f_\alpha \) is dominated by a function in \( F_{\gamma+\alpha} \), and

2. if \( \gamma < \omega \) and \( \alpha \geq \omega \), \( f_\alpha \) is dominated by a function in \( F_\alpha \).

**Proof of 1.** We proceed by induction on \( \alpha < \omega \).

For the base case \( \alpha = 0 \): we have \( f_0 = h \) dominated by a function in \( F_\gamma \) by hypothesis.

For the successor case \( \alpha = k + 1 \): by ind. hyp. \( f_k \) is dominated by a function in \( F_{\gamma+k} \), thus by (A.31) there exists \( p \) s.t. \( f_k(x) \leq F^p_{\gamma+k}(x+1) = F^p_{\gamma+k} \circ F_0(x) \). By induction on \( n \), we deduce

\[
f^p_k(x) \leq (F^p_{\gamma+k} \circ F_0)^n(x) ;
\tag{A.33}
\]

Therefore,

\[
f_{k+1}(x) = f^p_k(x) \tag{A.34}
\]

\[
\leq (F^p_{\gamma+k} \circ F_0)^x(x) \tag{A.35}
\]

\[
\leq F^{(p+1)x+1}_{\gamma+k}((p+1)x + 1) \tag{A.36}
\]

where the latter function \( x \mapsto F^{(p+1)x+1}_{\gamma+k+1}((p+1)x + 1) \) is defined by substitution from \( F_{\gamma+k+1} \), successor, and \( (p+1) \)-fold addition, and therefore belongs to \( F_{\gamma+k+1} \). □
A.8. Classes of Subrecursive Functions

Proof of 3. By (A.32), there exists $x_0$ s.t. for all $x \geq x_0$, $h(x) \leq F_{\gamma+1}(x)$. By lemmas A.13 and A.15, $f_{\alpha}(x) \leq f_{\alpha}(x + x_0) \leq F_{\alpha}(x + x_0 + \gamma + 1)$ for all $x$, where the latter function $x \mapsto F_{\alpha}(x + x_0 + \gamma + 1)$ is in $\mathcal{F}_{\alpha}$. \qed
Appendix A. Subrecursive Functions
Because their main interest lies in characterizing which problems are efficiently solvable, most textbooks in complexity theory concentrate on the frontiers between tractability and intractability, with less interest for the “truly intractable” problems found in $\text{ExpTime}$ and beyond. Unfortunately, many natural decision problems are not that tame and require to explore the uncharted classes outside the exponential hierarchy.

This appendix borrows its title from a survey by Friedman (1999), where the reader will find many problems living outside Elementary. We are however not interested in “creating” new problems of enormous complexity, but rather in classifying already known problems in some important stops related to the extended Grzegorczyk hierarchy. Because we wanted this appendix to be reasonably self-contained, we will recall several definitions found elsewhere in these notes.

### B.1 Fast-Growing Complexities

**Exponential Hierarchy.** Let us start where most accounts on complexity stop: define the class of exponential-time problems as

$$ \text{ExpTime} \overset{\text{def}}{=} \bigcup_c \text{DTIME} \left( 2^{n^c} \right) $$

and the corresponding nondeterministic and space-bounded classes as

$$ \text{NExpTime} \overset{\text{def}}{=} \bigcup_c \text{NTime} \left( 2^{n^c} \right) $$

$$ \text{ExpSpace} \overset{\text{def}}{=} \bigcup_c \text{SPACE} \left( 2^{n^c} \right) $$

Problems complete for \textsc{ExpTime}, like corridor tiling games (Chlebus, 1986) or equivalence of regular tree languages (Seidl, 1990), are known not to be in \textsc{PTime}, hence the denomination “truly intractable” or “provably intractable” in the literature.

We can generalize these classes of problems to the \textit{exponential hierarchy}

\[ k\text{-ExpTime} \overset{\text{def}}{=} \bigcup_c \text{DTIME} \left( 2^{\cdot 2^n c} \right), \]

with the nondeterministic and space-bounded variants defined accordingly. The union of the classes in this hierarchy is the class of \textit{elementary} problems:

\[ \text{Elementary} \overset{\text{def}}{=} \bigcup_k k\text{-ExpTime} = \bigcup_c \text{DTIME} \left( 2^{\cdot 2^n c} \right). \]

Note that we could as easily define \text{Elementary} in terms of nondeterministic time bounds, space bounds, alternation classes, etc. Our interest in this appendix lies in the problems found outside this class, for which suitable hierarchies need to be used.

\textbf{The Extended Grzegorczyk Hierarchy} \((\mathcal{F}_\alpha)_{\alpha < \varepsilon_0}\) is an infinite hierarchy of classes of functions \(f\) with argument(s) and images in \(\mathbb{N}\) (Löb and Wainer, 1970). At the heart of each \(\mathcal{F}_\alpha\) lies the \(\alpha\)th \textit{fast-growing function} \(F_\alpha : \mathbb{N} \rightarrow \mathbb{N}\), which is defined by

\[
F_0(x) \overset{\text{def}}{=} x + 1 , \quad F_{\alpha+1}(x) \overset{\text{def}}{=} F_\alpha^{x+1}(x) = F_\alpha(F_\alpha(\cdots F_\alpha(x)) ) , \\
F_\lambda(x) \overset{\text{def}}{=} F_{\lambda_x}(x) ,
\]

where \(\lambda_x < \lambda\) is the \(x\)th element of the \textit{fundamental sequence} for the limit ordinal \(\lambda\), defined by

\[(\gamma + \omega^{\beta+1})_x \overset{\text{def}}{=} \gamma + \omega^\beta \cdot x , \quad (\gamma + \omega^\lambda)_x \overset{\text{def}}{=} \gamma + \omega^{\lambda_x} .
\]

For instance,

\[
F_1(x) = 2x + 1 , \quad F_2(x) = 2^{x+1}(x + 1) - 1 , \\
F_3(x) > 2^{\cdot 2^{\cdot 2^{\cdots} x \text{ times}}},
\]

\(F_\omega\) is an Ackermannian function, 
\(F_{\omega^\omega}\) is a hyper-Ackermannian function, etc.
For $\alpha \geq 2$, each level of the extended Grzegorczyk hierarchy can be characterized as a class of functions computable with bounded resources
\[
\mathcal{F}_\alpha = \bigcup_c \text{FDTIME } (F^c_\alpha(n)),
\] (B.1)
the choice between deterministic and nondeterministic or between time-bounded and space-bounded computations being once more irrelevant because $F_2$ is already a function of exponential growth. In particular, $F^c_\alpha$ belongs to $\mathcal{F}_\alpha$ for every $\alpha$ and fixed $c$.

Every function $f$ in $\mathcal{F}_\alpha$ is honest, i.e. can be computed in time elementary in itself\cite{Wainer1970}—this is a variant of the time constructible or proper complexity functions found in the literature, but better suited for the high complexities we are considering. Every $f$ is also eventually bounded by $F_{\alpha'}$ if $\alpha < \alpha'$, i.e. there exists a rank $x_{f,\alpha}$ s.t. for all $x_1, \ldots, x_n$, if $\max_i x_i \geq x_{f,\alpha}$, then $f(x_1, \ldots, x_n) \leq F_{\alpha'}(\max_i x_i)$. However, for all $\alpha' > \alpha > 0$, $F_{\alpha'} \notin \mathcal{F}_\alpha$, and the hierarchy $(\mathcal{F}_\alpha)_{\alpha<\varepsilon_0}$ is strict for $\alpha > 0$.

**Important Stops.** Although some deep results have been obtained on the lower classes\cite{Ritchie1963}, we focus here on the non-elementary classes, i.e. on $\alpha \geq 2$, where we find for instance
\[
\mathcal{F}_2 = \text{FElementary},
\]
\[
\bigcup_k \mathcal{F}_k = \text{FPrimitive-Recursive},
\]
\[
\bigcup_k \mathcal{F}_\omega^k = \text{FMultiply-Recursive},
\]
\[
\bigcup_{\alpha<\varepsilon_0} \mathcal{F}_\alpha = \text{FOrdinal-Recursive}.
\]

We are dealing here with classes of functions, but writing $\mathcal{F}_\alpha^*$ for the restriction of $\mathcal{F}_\alpha$ to $\{0,1\}$-valued functions, we obtain the classification of decision problems displayed in Figure B.1.

Unfortunately, these classes are not quite satisfying for some interesting problems, which are non elementary (resp. non primitive-recursive, or non multiply-recursive, ...), but only barely so. The issue is that complexity classes like e.g. $\mathcal{F}_3^*$, which is the first class that contains non-elementary problems, are very large: $\mathcal{F}_3^*$ contains for instance problems that require space $F_3^{100}$, more than a hundred-fold compositions of towers of exponentials. As a result, hardness for $\mathcal{F}_3$ cannot be obtained for the classical examples of non-elementary problems.

\footnote{See Ritchie\cite{Ritchie1963} for a characterization of $\text{FLINSPACE}$, and for variants see e.g. Cobham\cite{Cobham1965}; Bellantoni and Cook\cite{Bellantoni1992} for $\text{FPTIME}$, or the chapter by Clote\cite{Clote1999} for a survey of these techniques.}
Figure B.1: Some complexity classes.
B.1. Fast-Growing Complexities

We therefore introduce smaller classes:

\[ F_\alpha \overset{\text{def}}{=} \bigcup_{p \in \cup_{\beta < \alpha} \mathcal{F}_\beta} \text{DTIME} \left( F_\alpha \left( p(n) \right) \right) . \] (B.2)

As previously, the choice of DTIME rather than NTIME or SPACE or ATIME is irrelevant for \( \alpha \geq 3 \). This yields for instance a class \( F_3 \) of non-elementary decision problems closed under elementary reductions, a class \( F_\omega \) of Ackermannian problems closed under primitive-recursive reductions, a class \( F_{\omega^\omega} \) of hyper-Ackermannian problems closed under multiply-recursive reductions, etc.

We can name a few of these complexity classes:

\[ F_\omega = \text{ACKERMANNIAN} , \]
\[ F_{\omega^\omega} = \text{HYPER-ACKERMANNIAN} . \]

Of course, we could replace in (B.2) the class of reductions \( \cup_{\beta < \alpha} \mathcal{F}_\beta \) by a more traditional one, like FLogSPACE or FPTIME, or for \( \alpha \geq \omega \) by primitive-recursive reductions in \( \bigcup_k \mathcal{F}_k \) as done by Chambart (2011). However this definition better captures the intuition one can have of a problem being “complete for \( F_\alpha \).”

A point worth making is that the extended Grzegorczyk hierarchy has multiple natural characterizations: as loop programs for \( \alpha < \omega \) (Meyer and Ritchie, 1967), as ordinal-recursive functions with bounded growth (Wainer, 1970), as functions computable with restricted resources as in (B.1), as functions provably total in fragments of Peano arithmetic (Fairtlough and Wainer, 1998), etc.—which make the complexity classes we introduced here meaningful.

An \( F_3 \)-Complete Example can be found in the seminal paper of Stockmeyer and Meyer (1973), and is quite likely already known by many readers. Define a star-free expression over some alphabet \( \Sigma \) as a term \( e \) with abstract syntax

\[ e ::= a \mid \varepsilon \mid \emptyset \mid e + e \mid ee \mid \neg e \]

where \( a \) ranges over \( \Sigma \) and \( \varepsilon \) denotes the empty string. Such expressions are inductively interpreted as languages included in \( \Sigma^* \) by:

\[
\begin{align*}
\llbracket a \rrbracket & \overset{\text{def}}{=} \{ a \} \\
\llbracket \varepsilon \rrbracket & \overset{\text{def}}{=} \{ \varepsilon \} \\
\llbracket \emptyset \rrbracket & \overset{\text{def}}{=} \emptyset \\
\llbracket e_1 + e_2 \rrbracket & \overset{\text{def}}{=} [e_1] \cup [e_2] \\
\llbracket e_1 e_2 \rrbracket & \overset{\text{def}}{=} [e_1] \cdot [e_2] \\
\llbracket \neg e \rrbracket & \overset{\text{def}}{=} \Sigma^* \setminus [e] .
\end{align*}
\]

\(^3\)An alternative class for \( \alpha \geq 3 \) is

\[ F_\alpha \overset{\text{def}}{=} \bigcup_c \text{DTIME} \left( F_\alpha \left( n + c \right) \right) , \]

which is often sufficient and already robust under changes in the model of computation, but not robust under reductions.

Yet another alternative would be to consider the Wainer hierarchy \( (\mathcal{H}_\beta)_{\beta < \varepsilon_0} \) of functions (Wainer, 1972), which provides an infinite refinement of each \( \mathcal{F}_\alpha \) as \( \bigcup_{\beta < \omega^{\alpha+1}} \mathcal{H}_\beta \), but its classes lack both forms of robustness: any \( f \) in \( \mathcal{H}_\beta \) is bounded by \( H^\beta \) the \( \beta \)th function of the Hardy hierarchy. What we define here as \( F_\alpha \) seems closer to \( \bigcup_{\beta < \omega^{\alpha+2}} \mathcal{H}_\beta^* \).
The decision problem we are interested in is whether two such expressions $e_1, e_2$ are equivalent, i.e. whether $[e_1] = [e_2]$. Stockmeyer and Meyer (1973) show that this problem is hard for $2^{O(n \log n)}$ space under LOGSPACE reductions. Then, $F_3$-hardness follows by an FE reduction from any Turing machine working in space $F_3(2^{O(n)})$ into a machine working in space $2^{O(n \log n)}$.

That the problem is in $F_3$ can be checked using an automaton-based algorithm: construct automata recognizing $[e_1]$ and $[e_2]$ respectively, using determinization to handle each complement operator at the expense of an exponential blowup, and check equivalence of the obtained automata in PSPACE—the overall procedure is in space polynomial in $2^{O(n \log n)}$, thus in $F_3$.

### B.2 $F_\omega$-Complete Problems

We gather here some decision problems that can be proven decidable in $F_\omega$, thanks to Dickson’s Lemma over $\mathbb{N}^d$ and to the combinatorial analyses of McAloon (1984); Clote (1986); Figueira et al. (2011). We therefore focus on the references for lower bounds.

Vector Addition Systems (VAS, and equivalently Petri nets), provided the first known Ackermannian decision problem: $\text{FCP}$.

A $d$-dimensional VAS is a pair $(x_0, A)$ where $x_0$ is an initial configuration in $\mathbb{N}^d$ and $A$ is a finite set of transitions in $\mathbb{Z}^d$. A transition $a$ in $A$ can be applied to a configuration $x$ in $\mathbb{N}^d$ if $x' = x + a$ is in $\mathbb{N}^d$; the resulting configuration is then $x'$. The complexity of decision problems for VAS usually varies from $\text{EXPSPACE}$-complete (Lipton, 1976; Rackoff, 1978; Blockelet and Schmitz, 2011) to $F_\omega$-complete (Mayr and Meyer, 1981; Jančar, 2001) to undecidable (Hack, 1976; Jančar, 1995), via a key problem, which is decidable but of unknown complexity: VAS Reachability (Mayr, 1981; Kosaraju, 1982; Lambert, 1992; Leroux, 2011).

**[FCP]** Finite Containment Problem

**instance:** Two VAS $V_1$ and $V_2$ known to have finite sets Reach($V_1$) and Reach($V_2$) of reachable configurations.

**question:** Is Reach($V_1$) included in Reach($V_2$)?

**reference:** Mayr and Meyer (1981), from an $F_\omega$-bounded version of Hilbert’s Tenth Problem. A simpler reduction is given by Jančar (2001) from the halting problem of $F_\omega$-bounded Minsky machines.

**comment:** Testing whether the set of reachable configurations of a VAS is finite is $\text{EXPSPACE}$-complete (Lipton, 1976; Rackoff, 1978). FCP provided the initial motivation for the work of McAloon (1984); Clote (1986). FCP has been generalized by Jančar (2001) to a large range of behavioural relations between two VASs. Without the finiteness condition, these questions are undecidable (Hack, 1976; Jančar, 1995, 2001).
**B.2. \( F_\omega \)-Complete Problems**

**Lossy Counter Machines.** A *lossy counter machine* (LCM) is syntactically a Minsky machine, but its operational semantics are different: its counter values can decrease nondeterministically at any moment during execution. See Chapter 3 for details.

**[LCM]** Lossy Counter Machines Reachability

*instance:* A lossy counter machine \( M \) and a configuration \( \sigma \).

*question:* Is \( \sigma \) reachable in \( M \) with lossy semantics?

*reference:* Schnoebelen (2010a), by a direct reduction from \( F_\omega \)-bounded Minsky machines. The first proofs were given independently by Urquhart (1999) and Schnoebelen (2002).

*comment:* Hardness also holds for terminating LCMs, for coverability in Reset or Transfer Petri nets, and for reachability in counter machines with incrementing errors.

**[LCMT]** Lossy Counter Machines Termination

*instance:* A lossy counter machine \( M \).

*question:* Is every run of \( M \) finite?

*reference:* Schnoebelen (2010a), from LCM.

*comment:* Hardness also holds for termination of Reset Petri nets.

**Relevance Logics** provide different semantics of implication, where a fact \( B \) is said to follow from \( A \), written “\( A \supset B \)”, only if \( A \) is actually *relevant* in the deduction of \( B \). This excludes for instance \( A \supset (B \supset A) \), \((A \land \neg A) \supset B\), etc.—see Dunn and Restall (2002) for more details. Although the full logic \( R \) is undecidable (Urquhart, 1984), its conjunctive-implicative fragment \( R_{\land, \land} \) is decidable, and Ackermannian:

**[CRI]** Conjunctive Relevant Implication

*instance:* A formula \( A \) of \( R_{\land, \land} \).

*question:* Is \( A \) a theorem of \( R_{\land, \land} \)?

*reference:* Urquhart (1999), from a variant of LCM: the emptiness problem of *alternating expansive counter systems*, for which he proved \( F_\omega \)-hardness directly from the halting problem in \( F_\omega \)-bounded Minsky machines.

*comment:* Hardness also holds for LR+ and any intermediate logic between \( R_{\land, \land} \) and \( T_{\land, \land} \)—which might include some undecidable fragments.

**Data Logics \& Register Automata** are concerned with structures like words or trees with an additional equivalence relation over the elements. The motivation for this stems in particular from XML processing, where the equivalence stands for elements sharing the same *datum* from some infinite data domain \( \mathbb{D} \). Ackermannian complexities often arise in this context, both for automata models (essentially register automata and their many variants) and for logics (which include logics with *freeze* operators and XPath fragments)—the two views being tightly interconnected.
[ARA] Emptiness of Alternating 1-Register Automata

**instance:** An ARA \( A \).

**question:** Is \( L(A) \) empty?

**reference:** Demri and Lazic (2006), from reachability in incrementing counter machines LCM.

**comment:** There exist many variants of the ARA model, and hardness also holds for the corresponding data logics (e.g. Jurdziński and Lazic 2007; Demri and Lazic 2009; Figueira and Segoufin, 2009, Tan, 2010; Figueira, 2012). See ATA for the case of linearly ordered data.

**Interval Temporal Logics** provide a formal framework for reasoning about temporal intervals. Halpern and Shoham (1991) define a logic with modalities expressing the basic relationships that can hold between two temporal intervals, \( \langle B \rangle \) for “begun by”, \( \langle E \rangle \) for “ended by”, and their inverses \( \langle B \rangle \) and \( \langle E \rangle \). This logic, and even small fragments of it, has an undecidable satisfiability problem, thus prompting the search for decidable restrictions and variants. Montanari et al. (2010) show that the logic with relations \( A\bar{A}B\bar{B} \)—where \( \langle A \rangle \) expresses that the two intervals “meet”, i.e. share an endpoint—, has an \( F \omega \)-complete satisfiability problem over finite linear orders:

**[ITL]** Finite Linear Satisfiability of \( A\bar{A}B\bar{B} \) Interval Temporal Logic

**instance:** An \( A\bar{A}B\bar{B} \) formula \( \varphi \).

**question:** Does there exist an interval structure \( S \) over some finite linear order and an interval \( I \) of \( S \) s.t. \( S, I \models \varphi \)?

**reference:** Montanari et al. (2010), from LCM.

**comment:** Hardness already holds for the fragments \( \bar{A}B \) and \( A\bar{B} \) (Bresolin et al., 2012).

### B.3 \( F\omega \)-Complete Problems

The following problems have been proven decidable thanks to Higman’s Lemma over some finite alphabet. All the complexity upper bounds in \( F\omega \) stem from the constructive proofs of Weiermann (1994); Cichoń and Tahhan Bittar (1998); Schmitz and Schnoebelen (2011). Again, we point to the relevant references for lower bounds.

**Lossy Channel Systems** (LCS) are finite labeled transition systems \( \langle Q, M, \delta, q_0 \rangle \) where transitions in \( \delta \subseteq Q \times \{?,!\} \times M \times Q \) read and write on an unbounded channel. This would lead to a Turing-complete model of computation, but the operational semantics of LCS are “lossy”: the channel loses symbols in an uncontrolled manner. Formally, the configurations of an LCS are pairs \( (q, x) \), where \( q \) in \( Q \) holds the current state and \( x \) in \( M^* \) holds the current contents of the channel. A read \( (q, ?, m, q') \) in \( \delta \) updates this configuration into \( (q, x') \) if there exists some
x' s.t. x' \leq_* x'' \text{ and } mx'' \leq_* x\text{—where } \leq_* \text{ denotes subword embedding—, while a write transition } (q, m, q') \text{ updates it into } (q', x') \text{ with } x' \leq_* x m; \text{ the initial configuration is } (q_0, \varepsilon), \text{ with empty initial channel contents.}

Due to the unboundedness of the channel, there might be infinitely many configurations reachable through transitions. Nonetheless, many problems are decidable \cite{AbdullaJonsson1996, Cecceetal1994} using Higman’s Lemma and what would later become the WSTS theory. LCS are also the primary source of problems hard for \( F_{\omega^\omega} \):

**[LCS] LCS Reachability**

*instance:* A LCS and a configuration \((q, x)\) in \(Q \times M^*\).

*question:* Is \((q, x)\) reachable from the initial configuration?

*reference:* Chambart and Schnoebelen \cite{ChambartSchnoebelen2008b}, by a direct reduction from \( F_{\omega^\omega} \)-bounded Minsky machines.

*comment:* Hardness already holds for terminating systems, and for reachability in faulty channel systems, where symbols are nondeterministically inserted in the channel at arbitrary positions instead of being lost.

**[LCST] LCS Termination**

*instance:* A LCS.

*question:* Is every sequence of transitions from the initial configuration finite?

*reference:* Chambart and Schnoebelen \cite{ChambartSchnoebelen2008b}, from LCS.

There are many interesting applications of these questions; let us mention one in particular: Atig et al. \cite{Atigetal2010} show how concurrent finite programs communicating through weak shared memory—i.e. prone to re-orderings of read or writes, modeling the actual behaviour of microprocessors, their instruction pipelines and cache levels—have an \( F_{\omega^\omega} \)-complete control-state reachability problem, through reductions to and from LCS.

**Embedding Problems** have been introduced by Chambart and Schnoebelen \cite{ChambartSchnoebelen2007}, motivated by decidability problems in various classes of channel systems mixing lossy and reliable channels. These problems are centered on the substring embedding relation \( \leq_* \) and called Post Embedding Problems. There is a wealth of variants and applications, see \cite{ChambartSchnoebelen2008a, ChambartSchnoebelen2010, KarandikarSchnoebelen2012}.

We give here a slightly different viewpoint, taken from Barceló et al. \cite{Barceloetal2012}, that uses regular relations (i.e. definable by synchronous finite transducers) and rational relations (i.e. definable by finite transducers):

**[RatEP] Rational Embedding Problem**

*instance:* A rational relation \( R \) included in \((\Sigma^*)^2\).

*question:* Is \( R \cap \leq_* \) non empty?

*reference:* Chambart and Schnoebelen \cite{ChambartSchnoebelen2007}, from LCS.
comment: Chambart and Schnoebelen (2007) call this problem the Regular Post Embedding Problem, but the name is misleading due to RegEP. An equivalent presentation uses a rational language \( L \) included in \( \Sigma^* \) and two homomorphisms \( u, v: \Sigma^* \rightarrow \Sigma^* \), and asks whether there exists \( w \) in \( L \) s.t. \( u(w) \leq_w v(w) \).

[RegEP] Regular Embedding Problem instance: A regular relation \( R \) included in \((\Sigma^*)^2\).
question: Is \( R \cap \leq_w \) non-empty?
reference: Barceló et al. (2012), from RatEP.

[GEP] Generalized Embedding Problem instance: A regular relation \( R \) included in \((\Sigma^*)^m\) and a subset \( I \) of \( \{1, \ldots, m\}^2 \).
question: Does there exist \( (w_1, \ldots, w_m) \) in \( R \) s.t. for all \( (i, j) \) in \( I \), \( w_i \leq_w w_j \)?
reference: Barceló et al. (2012), from RegEP.
comment: RegEP is the case where \( m = 2 \) and \( I = \{(1, 2)\} \). Barceló et al. (2012) use GEP to show the \( F_{\omega\omega} \)-completeness of querying graph databases using particular extended conjunctive regular path queries.

Metric Temporal Logic & Timed Automata allow to reason on timed words over \( \Sigma \times \mathbb{R} \), where \( \Sigma \) is a finite alphabet and the real values are non-decreasing timestamps on events. A timed automaton (NTA, Alur and Dill, 1994) is a finite automaton extended with clocks that evolve synchronously through time, and can be reset and compared against some time interval by the transitions of the automaton; the model can be extended with alternation (and is then called an ATA).

Metric temporal logic (MTL, Koymans, 1990) is an extension of linear temporal logic where temporal modalities are decorated with real intervals constraining satisfaction; for instance, a timed word \( w \) satisfies the formula \( F_{[3,\infty)} \varphi \) at position \( i \), written \( w, i \models F_{[3,\infty)} \varphi \), only if \( \varphi \) holds at some position \( j > i \) of \( w \) with timestamp \( \tau_j - \tau_i \geq 3 \). Satisfiability problems for MTL reduce to emptiness problems for timed automata.

Lasota and Walukiewicz (2008) and Ouaknine and Worrell (2007) prove using WSTS techniques that, in the case of a single clock, emptiness of ATAs is decidable.

[ATA] Emptiness of Alternating 1-Clock Timed Automata instance: An ATA \( A \).
question: Is \( L(A) \) empty?
reference: Lasota and Walukiewicz (2008), from faulty channel systems LCS.
comment: Hardness already holds for universality of nondeterministic 1-clock timed automata.

[FMTL] Finite Satisfiability of Metric Temporal Logic instance: An MTL formula \( \varphi \).
question: Does there exist a finite timed word \( w \) s.t. \( w, 0 \models \varphi \)?
Note that recent work on data automata over linearly ordered domains has uncovered some strong ties with timed automata (Figueira et al., 2010; Bojańczyk et al., 2011; Figueira, 2012; Bojańczyk and Lasota, 2012).

Currently, the known \( F_{\omega^\omega} \)-complete problems are all related to extensions of Petri nets called *enriched nets*, which include timed-arc Petri nets (Abdulla and Nylén, 2001), data nets and Petri data nets (Lazić et al., 2008), and constrained multiset rewriting systems (Abdulla and Delzanno, 2006). Reductions between the different classes of enriched nets can be found in (Abdulla et al., 2011; Bonnet et al., 2010). Defining these families of nets here would take too much space; see the references for details.

**[ENC]** Enriched Net Coverability

*instance:* An enriched net \( \mathcal{N} \) and a place \( p \) of the net.

*question:* Is there a reachable marking with at least one token in \( p \)?

*reference:* Haddad et al. (2012), by a direct reduction from the halting problem in \( F_{\omega^\omega} \)-bounded Minsky machines.

*comment:* Hardness already holds for bounded, terminating nets.

**[ENT]** Enriched Net Termination

*instance:* An enriched net \( \mathcal{N} \).

*question:* Are all the executions of the net finite?

*reference:* Haddad et al. (2012), from [ENC].
